Casein carbon printing .....	578
"pigment" process .....	578
Celluloid, cementing to paper .....	731
exhibition, Berlin .....	49
in Japan .....	34, 482
printing from wet negative through (Pat.) .....	816
substitute .....	619, 653
test negatives .....	635
"Celluloid and Verarbeitend" (Rev.) .....	684
Cerant, studio, useful (Anal.) .....	875
Ceramic photographs (Pat.) .....	382, 497
imitation (carbon) .....	60
Ceric salts, carbon with (Pat.) .....	551
Cerio Photo Printing Co., winding-up .....	743
Changing-bags, making (Anal.) .....	571
boxes, daylight loading (Pat.) .....	57
in the studio .....	114
(See also <i>Exposing Plates and Films</i> .)	
Chapman, H. A., president, P.P.A. .....	217
Chemical equations and photographic investigation .....	447
Child photography, hints on .....	22, 537
a master in .....	581
China, photographs on (Pat.) .....	169
Christmas cards, making photographic (Soc.) .....	117
Chromate of copper process .....	738
Crome alum, impurities in (Ans.) .....	16
Cinematograph accidents .....	7, 223
entertainments .....	317
exhibition and L.C.C. .....	108
international .....	228
examinations .....	211
films, copyright in .....	446, 587
fireproof .....	355
Lumière .....	298
moistening (Pat.) .....	953
repairing (Pat.) .....	910
rust prevention .....	947
in Mexico .....	945, 967
"Kinora" (Rev.) .....	344
lenses (Pat.) .....	802
mechanism (Pat.) .....	798
45, 104, 164, 260, 310, 331, 382, 402, 479, 570, 591, 741, 891, 914, 969, 104, 402, 536	
phonograph (Pat.) .....	104, 617, 687
portraits .....	330, 515
reflecting bands (Pat.) .....	647
regulations in Middlesex .....	272
scandals in France .....	877
shutters (Pat.) .....	408
Cinematograph at Urbanora House .....	361
in colour, Smith .....	960
three-colour (Pat.) .....	740
"Cinematographie, Die" (Rev.) .....	165
Handbuch der Praktischen, Liesegang (Rev.) .....	404
Clock, dark-room (Pat.) .....	45
"Ensign" (Rev.) .....	381
Welborne Piper (Rev.) .....	386
Coal, action on photographic plate, W. J. Russell .....	869
Coburn, caricature of .....	333
Coin-in-slot camera (Pat.) .....	935
Colloid emulsion, orthochromatic .....	418
Colloidion P.O.P., black tones. By W. Foster Brigham .....	20
"Ilford" (Rev.) .....	291
malt, Grayson (Rev.) .....	126
printing on (Anal.) .....	336
"Rajar" (Rev.) .....	517
self-toning, Kodak (Rev.) .....	742
stains on .....	165
"thio", toning .....	492
"Colloidchemie und Photographie" (Rev.) .....	571
"Colloides Silber und die Photographie" (Rev.) .....	572
Colloids, chemistry and physics of .....	452, 489, 488, 529
Shepherd .....	368
Colotype printing (Soc.) .....	288, 449
Colour Photographers, Society of, exhibition .....	668
"Colour Photography" (Rev.) .....	445
Colour photography and crime .....	740, 960
animated .....	440
cameras, one-exposure .....	29
Donisthorpe process (Pat.) .....	942, 965, 979
Lippmann. By H. E. Ives .....	331
"Rothé" method .....	925
pinatype (Soc.) .....	590
projection "prismoids" (Pat.) .....	607
rotating disc, three-colour method (Pat.) .....	41
screen-plate processes .....	873
ceramic. Palmer (Pat.) .....	796
dyed, Lambert (Pat.) .....	797
hexagon. Child (Pat.) .....	44, 330
Krayn (Pat.) .....	515
compensating filter. Brasseur (Pat.) .....	625
Wand-rsleb (Pat.) .....	557
Lumière, new .....	459
Sanger-Shepherd (Pat.) .....	873
Szczepanski .....	812, 765, 802, 918
"Thames" .....	884
By H. Essenhigh Corke .....	862
thread. Masser & Hudson (Pat.) .....	589
Wratten (Pat.) .....	243
copying. Brasseur (Pat.) .....	702
Child (Pat.) .....	111
Wedmore (Pat.) .....	219
three-colour bleach-out process (Pat.) .....	445
transparencies by artificial light .....	157
Colour untinted photographic films. By Dr. Karl Schaum .....	157
multi-, prints on single plate (Pat.) .....	624
screen holders (Pat.) .....	331
prints, Percival Small's (Rev.) .....	761
pseudo-steroscopic effects .....	328, 335, 350
Coloured objects, photography of, in principle and practice. By C. E. K. Mees .....	735, 754, 770, 788
Colouring photographs (Pat.) .....	593
Combination group-negative .....	751
Combining, printing, rubber & adhesive in .....	606
Combined bath (Anal.) .....	669
fixing P.O.P. prints before toning .....	886
Commercial record photography .....	549

## PATENTS, AUTHORS OF—continued.

	PAGE		PAGE
Rottgen, J., & Frey, J.—printing machine	569	Plate "Process" and "Process Panchromatic,"	
Ruppel, R. F. F.—coin camera	985	Wratten (Rev.)	49
Rousset, J., & Muller, J. L.—glass plate cine-		" "Professional," Griffin (Rev.)	256
matographs		" "Studio," Barnet (Rev.)	255, 893
Roux, F. A.—metal printing plates	647, 667	sped numbers	104
Rubenking, J. H.—negative washer	930	Plate-holders (Pat.)	310
Ruiter, J. de—sensitisers	146, 164	(See also <i>Exposing Plates and Films</i> )	
Sabroe, T. T.—mercury-vapour cylinder printers	146	Plate-markers, "Leto" (Rev.)	166, 840
Sanderson, A. W. S.—tripod shoe	70	Plate-marking, burnishing and embossing. By	
Sandman, M.—collodion-lined amm. electros	778	W. Michell	375
Schmidt, H.—mounting P.O.P.	913	postcards (Rev.)	499, 817
Schmidt, J.—arc lamps	384	Plates at different temperatures, sensitiveness of	661
Schuster, R.—colour printing	514	By H. J. Wallace	125, 473
Schwarz, A.—screen plates	874	Plates, daylight loading (Pat.)	
Scopes, A. G., & Alliance, Ltd.—embossed		(See also <i>Exposing Plates and Films</i> )	
photographs	460	Platino-type Co.'s annual outing	724
Seale, G. B.—rite cameras	402	Platino-type paper, black "Japine" (Rev.)	893
Shawcross, H. L.—ferrie-ink process	759	" "reduction in price	440
Shepherd, E. Sanger—colour filters	459	" "practical (Soc.)	117
"—screen plates	459	" "dispute	167
Sherrick, A.—developing tanks	646	" "fraudulent substitution of bromides (Cor.)	594
Slm, H. V.—cylinder printers	289	Platinum papers, "mercury" sepia, Jacoby (Rev.)	31
Simon, H., & Voss, H.—cinematograph portraits	515	(Cor.)	181
Smith, H. E.—thymolobdate toning	853	Poisons Act, projected	131
Spitzer, E.—litho engraved plates	514	Ponting's, H. G., photographs	214, 273, 821
Staley, A. E., & Wheeler, O.—telescope lenses	183	P.O.P. agar-agar (Pat.)	70
Starnes, F. C., Bates, A. G., & Wellcome, H. B.—		" "combined bath for black tones	29
thiostannate toning	44	" "alteration of prints	810
Sternbergh, L. M.—focussing mirror	330	" "fixing before toning	586
Stokes, F. W. S., & Hillman, C. J.—mercury-		" "finishing and mounting (Anal.)	950
vapour cylinder printer	220	" "gazing	30
Strecker-Aufmeyer, H.—electrolytic etching	198	" " (Cor.)	110, 131
Szczepanik, J.—colour screen-plates	682	" "halide contents of. By R. E. Blake Smith	791
Thornton, J. E.—reflex cameras	684	" "hypo-alum toning (Anal.)	332, 424, 545, 669
"—self-developing roll film cart-		" "ink impressions on (Cor.)	482
ridges	834	" "Ivory" (Rev.)	255
Thornton-Pickard Manufacturing Co.		" "mounting (Pat.)	913
(See <i>Pickard, A. G.</i> )		" "postcards, "Indiana" (Rev.)	931
Topp, M. N.—stereoscopic projection	435	" "printing, extreme measures in	599
Traube, A.—diachrome toning process	495	" "prints, reducing	245, 600
Truscott, C. P.—reflex camera level	889	" "nature of image. By R. E. Blake Smith	142
Turner, J. W., & Nicholls, G. R.—reflex cameras	497	" "self-toning. By H. E. Smith	490
Tyler, W.—print washers	740	" "thiocarbamide bath for	142
Ullmann, M.—half-tone blocks direct in camera	918	Portrait prints direct in the camera	897
Verge, A. E., & Ossart, G. A.—conchoid lenses	45	" "American rights in	897
Voss, H., & Simon, H.—cinematograph portraits	515	" "at the Royal Academy winter exhibition, By	
Wanderlich, E.—increased light filters	825	F. C. Tilney	21
Watkins, A.—time-development calculator	946	" "photographic and impressionist	19
Wedmore, E. B.—copying screen-plate trans-		Portraits by artificial light.	
parencies	797	(See <i>Arc-lamps, Gas, Mercury-vapour.</i> )	
Weinberg, B.—stereo-cinematograph projection	704	" "flashlight in professional. By C. R. Ogilvie	376
Wellcome, H. S., Bates, A. G., & Starnes, F. C.—		" "hints on. By J. W. Little	908, 923, 941
thiostannate toning	44	" "home	830
Wells, A.—slit-lamp	436	Portugal, German photographic trade with	903
Werner, P., & Pohle, F. W. C.—posing attachment	473	Posing attachment (Pat.)	830
Wheeler, O.—lens hoods	473	Posing for engravings	479
Wheeler, O., & Staley, A. E.—telescope lenses	183	Positive prints direct in camera	598
White, A.—printing frame	796	" "lantern-slides and paper prints direct in	
Wilkinson, J. & A.—printing frames	7	" "cameras by a reversal process	811, 843, 858

## SUMMARY.

Some of the anomalies in plate speed numbers are the subject of a note on page 1.

A non-shift printing-frame is the only patent of the week. (P. 7.)

Drying marks in a negative, according to a recent writer, may be removed by bleaching and re-developing. (P. 6.)

Professor Namias has modified the permanganate reducer, which under the new formula may be made up as a dry powder. (P. 2.)

The views of a Californian woman photographer on business matters of the reception-room are printed on Page 4.

Mercury-vapour and arc lamps, pinhole exposures, and the telegraphic transmission of photographs occupy our correspondence columns this week. (P. 13.)

A trick which could easily be played on a photographer of public events is mentioned on Page 2 in reference to a recent instance.

A sharp reproof to a young Jewess, summoned for a canvassing fraud, was administered in the Clerkenwell Police Court last week. (P. 11.)

Some views of members of the photographic trade on the annual index to the "B.J." appear on Page 5.

## "COLOUR-PHOTOGRAPHY" SUPPLEMENT.

Mr. F. Martin Duncan gives some hints from his pioneer experience in the use of the Autochrome plate in natural science. (P. 1.)

M. Gravier explains the device used by him for daylight development of the Autochrome plate by the method in which only three solutions are used. (P. 7.)

We give particulars of the apparatus used by Dr. H. Lehmann in the Lippmann process. (P. 2.)

M. Cheron has further improved his apparatus for the prismatic dispersion process. A description of the new construction is given on Page 3.

An abstract translation of Baron von Hübl's recent paper on the Autochrome plate appears on Page 5.

An exhibition of Autochromes and three-colour prints remains open at the Polytechnic, Regent Street, until to-morrow (Saturday), 10 p.m. (P. 8.)

M. Lumière père has been fêted by journalistic and other admirers in America. (P. 8.)

## EX CATHEDRA.

**A Prosperous New Year.** Few occasions in the course of the year afford us quite the same pleasure as that which makes us the recipient of Christmas greetings from readers of the JOURNAL in all parts of the kingdom and in distant countries. We hope to be pardoned for expressing a sense of gratification at the fact that not a few of these seasonable greetings contain a word of thanks for some small service which we have been able to render the writers. To them and to all before whom these lines come we reply with all the good wishes of the season, and hope for them the prosperity which they would desire for themselves in 1908.

\* \* \* \* \*

**Milky Collodion.** An article in our last issue dealt with the enamelling of prints with collodion, and it may therefore be useful to some desirous of carrying out the process if we draw attention to a trouble frequently met with by those unfamiliar with collodion and its use. If the collodion is in perfect condition it should give an absolutely clear and transparent film upon a glass plate, but in the hands of those unaccustomed to it a milky or opalescent film is frequently produced. This is due to the presence of water which has found its way into the solution. The alcohol and ether, which are the solvents used in the preparation of collodion, greedily absorb water from a damp atmosphere, therefore the solution should be kept well stoppered and in a dry, but cool, place. Most frequently, however, the water is introduced by the use of a damp measure or bottle. When collodion is bought in small quantities from a photographic dealer it is always advisable to warn him that the bottle used must be rinsed out with spirit before it is filled, and the purchaser should be careful to take the same precaution himself if he has occasion to transfer the solution to any other vessel. Similar care must be taken when purchasing "thinning solution," or the alcohol and ether required for making it up, and, in the latter case, it is necessary to go to the expense of procuring absolute alcohol if one wishes to ensure a perfectly clear coating. For the simple purpose of enamelling prints a little milkiness may not be of much consequence, but it is of no benefit, and the collodion may be required for other purposes for which absolute clearness is essential.

\* \* \*

**Tables of Plate Speeds.** Some experimental work on which we have recently been engaged has again drawn attention to the unreliable character of some published tables of plate speeds. We were comparing effects produced on two plates, which we will call A and B, and our tests at first were conducted under the impression that the two plates were of equal speed, or

nearly so. Some tables that we consulted gave them as equal, while others classed A as slightly faster than B. The anomalous results we obtained proved, however, that something was seriously wrong, and a test showed that in spite of all the tables A was only half the speed of B. Curiosity led us to consult various tables of speeds, including some a year or more old and others that were quite recent. As is well known, some of these tables are only published once a year, while others are issued at very frequent intervals. It might be assumed that the latter must be more reliable, as they are more frequently revised, but our little research seemed to show quite a different state of affairs. In one of the frequently "revised" lists these two plates have retained the same speeds for two years past, A being described as faster than B, but in a set of yearly lists it is noticeable that B has been steadily rising in speed until it is now double the rapidity of two years ago. Evidently these yearly lists have been subject to revision while the others have not, which state of things can only lead to a lack of confidence in plate speeds in general. We notice that, in the case of sundry other plates, speeds have altered considerably in the last year according to some lists, while others show no variation at all. It stands to reason that the speeds, if reasonably correct, should not differ in this manner, therefore we suggest that those responsible for the compilation of these various lists would be well advised to overhaul them thoroughly and re-test the plates they refer to.

#### **The Permanganate Reducer.**

A note in "Eder's Jahrbuch" by Professor Namias draws attention to a modification in the permanganate reducer which may be of service, particularly in preparing the reducer in a dry state for solution at the time of use. Professor Namias dispenses with sulphuric acid, using instead ordinary alum, the acid character of which is apparently sufficient for the purpose. He adds one-fifth of one per cent. of potass. permanganate to a cold saturated solution of alum; in other words, the reducer contains about 1 grain of permanganate and about 50 grains of alum per fluid ounce. Thus compounded, it is found to work better than the sulphuric acid formula, as it keeps well and does not attack the gelatine film. The alum-permanganate solution stains the gelatine a deeper brown than the acidulated bath owing to the precipitation of manganese oxide; by the use of a 5 per cent. solution of sodium bisulphite this stain can be readily removed.

#### **Copyright Hardships.**

The difficulties which surround the law of copyright are sometimes brought home unpleasantly to the photographer, as witness a case which, in one form or another, is constantly being brought before us. Reference to a recent instance may save some of our readers from taking futile measures for the redress of an actual—but, unfortunately, not a legal—wrong. A photographer, at a good deal of trouble, obtained permission to photograph a football team of some importance. The players were grouped during an interval in the game at one corner of the ground, and while the favoured photographer was making his exposures a snapshot of the group was taken by the operator of a firm making a specialty of press photography. This snapshot, which was to all intents and purposes a facsimile of that taken by the photographer who had arranged the group, was reproduced in a sporting paper in preference to the other because it was submitted earlier. The photographer naturally feels that his rights in the arrangement of the players have been infringed, yet we can only assure him that he will be wise to stomach the trick played on him. If he is not he should be pre-

pared to fight the issue in the High Courts, for there is no case within our recollection which supports him in his alleged proprietorship of copyright in the arrangement of the group. What cases there are against him, and support the view that—in the legal sense—a group of footballers is to be classed with other "works of Nature," which it is the right of any person to represent, notwithstanding that there may be copyright in some representation of such scene or object. We are free to admit the argument that the photographer, as the person who superintends the arrangement of a portrait or group, is the author of the copyright, and that therefore his work is entitled to protection; but the point is one full of the nicest legal distinctions, and might travel from court to court before it was settled. We would recommend our friend in future to employ, in place of legal procedures, an able-bodied assistant to keep his competitors away.

**Cold Weather.** In a recent article on the effect of temperature in producing flat prints by the oil and bromoil processes, we drew attention to the necessity of preserving a constant temperature of about 65 deg. Fahr. if the latter process is to be worked successfully. In the course of our experiments on the effect of temperature we observed what appeared to be a curious fact, and is perhaps worth mention, seeing that it may be of some slight importance in the case of other photographic processes. When working in hot summer weather we frequently met with trouble due to the use of solutions at too high a temperature. For a short period during the last summer we were forced to work with solutions the temperature of which was rather above 70 deg. Fahr., and in many cases damage to the gelatine resulted. The gelatine dissolved away in the high-lights of the image, while the shadows were so softened that pigmentation produced reversed or negative images. During the recent cold weather we have, however, used upon the same papers solutions warmed to about 75 deg. Fahr. without meeting with any trace of reversal. In a few cases the high-lights showed signs of washing out, but the damage done was by no means comparable with that produced by slightly cooler solutions in the summer. We have, indeed, produced good results at a temperature of 80 deg. in the winter on emulsions that were practically destroyed at 70 deg. in the summer, though 65 deg. is the average working temperature that we recommend. These facts suggest that in cold weather the gelatine is somewhat more resistant than in summer, though it is not at all clear why it should be so. Whether similar conditions prevail in the case of development we do not know, and possibly this point might be worth testing.

**The Fineness of Grain in Negatives.** In our issue of December 13 we published a paper, read before the French Photographic Society by M. Monpillard, entitled "Experiments on the grain of silver images obtained in the wet collodion process." In it the author says that the size of the grains reduced in wet collodion negatives may be larger than those in some gelatine plates, yet the definition of fine lines in a wet collodion is invariably better than that obtained on a gelatine plate of moderate speed. This is pretty generally well known to those who make negatives for process work and other mechanical processes. M. Monpillard also points out that there is a considerable difference in the size of the grain according as to whether iron or pyrogallie acid is employed as the developer. He also alludes to different salts, used for iodising the collodion, having an influence on the size of the grains of the reduced silver. In conversation with a very old worker of the collodion process a few days ago, he told us that in the

middle or late "fifties," when micro-photographs (that is, minute photographs to be shown under the microscope) were exciting some interest, he was ambitious of producing one of the front page of the "Times" within the space of the tenth of an inch, so as to be readable under the microscope. He said he did not succeed, as the particles of reduced silver were too large to form the small letters, though the large capitals were readable. The collodion used was salted with iodide of potassium—no bromide—and the developer was pyrogallic acid. Our informant found that the condition of the bath had a very material influence on the size of the grain of the reduced silver—a point not alluded to in the paper of M. Monpillard. If the bath was quite neutral, or rather on the alkaline side, according to litmus paper, and in the best working order, the grain was exceedingly fine. The image, by transmitted light, was somewhat of a claret colour, and partook more of the appearance of a stain than a real deposit of metallic silver. With an acid bath the grain was larger, and if the acidity was increased the grain, up to a point, became still greater in size.

\* \* \*

#### Unique Photographs.

It is not often that the landscape photographer secures a result that can justly be described as unique. Given the same landscape, some other photographer may repeat his result at any time, provided some extraordinary cataclysm does not destroy the landscape, and even if such a catastrophe does occur the chances are that many have previously secured photographs of the scene. The San Francisco earthquake has, however, afforded an opportunity that is, we believe, without a parallel in photography. As a result of the earthquake a new island appeared in the neighbourhood of the Bogoslof Islands. For long the water about the island was so hot as to make the new land unapproachable, but at last a revenue schooner got near enough to photograph it. Still later, a party succeeded in landing, and secured a few more photographs. These are the first and the last photographs to be taken, for the island very soon afterwards disappeared.

\* \* \*

#### The Exchange of Photographs.

A most ambitious scheme is put forward in the current issue of the "Revue Internationale de Photographie," the photographic organ of the Institut Bibliographique et Photographique of Brussels. It is suggested (1) that a list should be made of existing collections of photographs, and (2) that a directory of photographers interested in the application of photography to some branch of pure or applied science should be compiled. Without knowing to whose initiative these promulgations are to be ascribed, it may be permissible for us to say that the scheme appears to be one of those things which appear highly desirable to one or two persons and are therefore thought by them as likely to be enthusiastically received by many other persons. The scheme may be admirable—we are not saying it is not—but we would prophesy that every atom of time or money spent on it will be thrown away. In the first place, a list of private collections of photographs can only be made at great expense and without prospect of a remunerative return. Secondly, photographers taking photographs illustrative of science of some sort or another do so as much for the pleasure of the work as for any object they may have in using the finished prints: very little use would be made, in our judgment, of an exchange system. And even supposing we could find a good word to say for the above ideas, we should wish to see the suggestions of a scheme described as "international" in its aims put forward in more lucid English than that of such sentences as: "To get quickly an appreciable result, it would be

sufficient to publish the questionnaire below mentioned, and to send the answers to the 'Institut International de Photographie,' which will class them, and will be able to give satisfaction to every demand."

#### PHOTOGRAPHY OF 1907.

If one were limited to two words in which to summarise the photographic character of the year which has just closed, these two words could only be colour and oil. There can be no doubt that the photographic event of the year, and one which will have an influence on the immediate future of photography, has been the introduction of the Lumière Autochrome plate, and the consequent indulgence on the part of the veriest tyro in the use of the camera in colour photography. In thus bringing colour photography within the reach of every one, the Lumière Brothers may congratulate themselves that they have applied a gentle and agreeable stimulant to any who, but for it, would have dropped the camera for some hobby with more spice of novelty in it. The fascination of colour has been sufficient to give fresh zest to the practice of the art, whilst the possibilities which the Autochrome and its sister processes hold out of colour prints on paper by an easy process, will mean that those who have once taken an interest in the new departure will not allow their attention to wander. Moreover, it is certain that the facility of obtaining a record—even a transparency on glass—in colour has induced still others to take up photography who would never have done so without that encouragement. Thus, altogether, there is every reason to think that colour photography has taken a place among the regular branches of the art of the camera which it did not occupy previously, successful as were the processes—such as the Sanger-Shepherd—which preceded the Autochrome and are now its contemporaries.

The oil process cannot be claimed for the past year, but has, nevertheless, during this period, realised the hopes which were expressed in regard to it on its first announcement by Mr. Rawlins in the pages of our contemporary, "The Amateur Photographer," now three years ago. The stimulus to investigate its possibilities in pictorial photography was undoubtedly applied in this country by the exhibition of the prints by M. Robert Demachy at the Royal Photographic Society in the early part of last year, a repetition of the incident of some six years ago, when the exhibition of the American School at Russell Square aroused the most diverse opinions, was despised and imitated by opposite factions, and has now been almost forgotten. We would not think that the labours of MM. Demachy and Püyo, in bringing the oil process to the front, will meet quite the same unkind fate which has attended the "movement" of Mr. Holland Day and his collaborators. Good technicians that they are, the French workers earn the respect even of those who may not see eye to eye with them in the choice of methods, and, what is more, they are no mystery men as to their processes, nor is some fluent jargon on art the whole of their qualification to be heard. Mr. Rawlins may plume himself not a little on the fact that he has divorced M. Demachy from gum-bichromate and brought the oil process to consort with his (M. Demachy's) skilled hand, good taste and pretty fancy in things pictorial. And the English workers, such as Dr. Evershed, Mr. Mummery, and Mr. Welborne Piper, who, for technical or pictorial reasons, have interested themselves in the process, are still another link in the chain which further strengthens the bond uniting us with our Gallic neighbours. Quite a small entente cordiale in its way.

In other respects it cannot be said that there is a great

deal to mark out 1907 as a year of photographic note. An exception is the combined carbon and bromide paper introduced by the Rotary Photographic Company, and affording very similar facilities to those permitted by Mr. Manly's Ozobrome process. In the way of apparatus the year has seen the widespread adoption of the reflex

camera by all classes of makers, whose various patterns of instruments total up to a goodly figure. If reports be true there are to be still further developments in the reflex as a universal instrument, and one new introduction which may be mentioned in this connection is a folding reflex brought on to the market by a Continental firm

## APPOINTMENTS AND ORDER-GETTING.

[That the American photographer is far fonder than is the British professional of meeting in conference for the discussion of business topics is a fact which is recognised by those who know both sides of the Atlantic. Hence one is not surprised to find in the American journals the papers read before the many photographic associations in the States composed wholly of professional photographers. Practical usefulness is usually the keynote of these contributions: it certainly is of the following paper by Miss E. F. Hannavan which we find reported in "Camera Craft" as having been delivered before the Photographers' Association of California. It deals with a theme on which too much thought cannot well be expended by the photographer.—Eds. "B.J."]

I SHALL not attempt to tell you anything new in regard to reception room methods; simply remind you of what I consider the few most important points to observe in meeting the patron. Before proceeding to the subject matter I wish to say just a few words concerning the appearance of the reception room and the dressing rooms, which in most studios are under the supervision of the lady receptionist. Keep them as orderly as possible each day, not some days. Do not leave prints scattered about, but return them to their places in folios which you should have systematically arranged. Have at hand a few choice prints to show any particularly appreciative patron, in a separate folio. Arrange greens or cut flowers about your studio when obtainable. I have found them to be a valuable asset, often opening the way to some interesting conversations. After sitters leave, re-arrange the dressing rooms.

### Types of Patron.

Not the least important part of the reception room equipment is the lady in attendance. She must be refined, enthusiastic and sympathetic; never mechanical. With her rests the success or failure of the business, assuming, of course, that good photography is the rule of the studio. Meeting the patron, as she does, so many times, it is very necessary she be philosophical in temperament and be able to approach advantageously the many varying characters, not all of whom are thoroughly agreeable, either. I will mention a few familiar types, and I am sure you will all recognise each and every one of them. One that is not altogether pleasant is the amateur. He informs you with a warning tone in his voice that he knows something about photography. Only yesterday I met such a one in our studio, one who was very amusing, and I believe you would have thought so, also, had you been present. He came in with no small amount of importance in his bearing. Following is the conversation:

"Can you take a group of three people in this studio and focus them properly? Understand me, get the correct focus on them." I knew at once he was an amateur.

"Yes, I think we can," I replied, and proceeded to show him several prints of groups of three and more. After scrutinising them closely he said:

"Yes, those are all in focus. The photographer must use a wide-range lens." After making a few further remarks, he drew from his wallet several 3 x 4 prints taken by himself, which he offered for inspection. They were everything but good.

Another type is the very plain young lady who brings in a picture cut from a newspaper or magazine and expresses a wish to be posed in the same manner. The pose is nearly always entirely inappropriate for her. The stout lady nearly always returns for a re-sitting. She knows she is stout, but thinks Mr. Photographer has made her look much stouter than she really is. Then there are the rush-order patrons. Compar-

tively speaking, they are in the minority. When you meet one I think it is the best policy to do your utmost to get his order ready for him on the date he specifies.

When a person enters the studio I presume at once he or she is interested in our photographs. After bidding the time of day, I nearly always open conversation with the remark, "You wish to look at some photographs?" The answer usually informs me as to who they are, and I proceed to show several specimens of photographs that I think would be appropriate; all this time getting at their idea by their remarks, and at the same time mentally diagnosing their financial condition.

### Tact in the Reception Room.

Patrons may be divided into two classes: those who care for low-toned artistic prints and those who prefer clear-cut pictures with a marble finish in human likeness. Unless asked, I never disclose a preference for fear of offending. Until they specify, I never show small sizes. Showing the larger prints, I nearly always take a frame of an exclusive design from a cabinet conveniently at hand and carefully arranged and lay it on the print, adding fifty per cent. to its appearance and also preserving the photograph, another important point to mention. Besides, my patron discovers that we also have a choice line of frames. Next I show some carefully tinted photographs of the best available subjects. This must be done smoothly, else it will be too apparent you are a clever saleswoman. Be clever, but conceal it. Put your heart into your salesmanship. Be enthusiastic over the beautiful prints you display and you are sure to transmit some of your enthusiasm to your customer. We want people to get the picture habit. We may not sell all we have suggested, but the total increase of sales for the month will be better than if we had shown only plain photographs and waited for a few to ask if we sold frames and did tinting. Talk about large work and call attention to a few choice artistically framed specimens upon the walls. At a later day your patron may wish something in that line. Spend as much time as you can spare with every prospective customer. They will be more apt to return and feel that much more at ease and at home when they do. Do not quote prices by the dozen. A negative will give off more or less than a dozen. Give the price for the first print and the duplicate price per print. I have found this invariably leads to the ordering of larger work, patrons feeling that they can order at their own convenience.

### Booking a Sitting

Lay particular stress upon the necessity of making an appointment for a sitting. Do not allow patrons to think they can drop in at any time and be accommodated at once. Failing to do this is not conducive to the impression that yours is a busy studio. If they do come when the photographer is busy, the man, woman or child, as the case may be, becomes impatient and ruffled—

something to be absolutely avoided in a studio. A visit to the studio must be a pleasure trip from the beginning to the end. So much for the prospective patron.

The patron has now come for the sitting, according to an appointment which has either been phoned or written. I register the name, address, and order, and collect something on the account. I prefer this method because one is invariably busy with another customer when this first sitter is finished. On a printed slip which I hand the photographer, are all particulars. We use this also for recording the number of exposures made, size of plates and the like.

The customer next visits the studio for the proofs, if they were not to be posted. It is much better to have patron call for proofs, if possible, because you then have another opportunity to talk up the good points of several proofs; thus bringing up the sum total of the order to a higher point. Try to look over proofs carefully before the sitter calls for them, so that you can talk intelligently, and to the end that the patron feels you have been interested enough to give them this previous attention. Be sure to get the opinion of the party who made them. This, I find, always carries a great deal of weight.

### System in Fulfilling Orders.

In closing, just a few words on the delivery of the photographs. By looking at your cards in the order drawer you know each day what orders are promised. I take it for granted you use the card system, as it is by far the best. Attend to this each morning, and if the entire order is not ready, have as many as can be completed for the date promised. In delivering the pictures appear as interested as you were in getting the orders. Do not be indifferent or mechanical. If the pictures are not just to the patron's liking, find out what the objection is and have them altered. This is the only way to increase your list of patrons and hold those you already have. Suggest framing or tinting some of the prints, should opportunity present, whatever they specified when they first interviewed you, should opportunity again present. I believe that in a photographer's reception room, as well as in a department store, the power of suggestion needs to be used continually. The methods I have outlined appeal to me the best, even after visiting a great many different studios and observing the methods employed.

E. F. HANNAVAN.

## ALUM-HYPO BATHS FOR THE SIMULTANEOUS FIXING AND HARDENING OF PLATES AND FILMS.

[Many formulæ for alum fixing-baths are to be found in the text-books, but few, we imagine, which are the result of experiments, such as the following by Professor Namias, which we translate here from our contemporary "Das Atelier des Photographen." The writer, after examining a number of preparations for the composition of a hypo-alum fixing-bath, gives the palm to a mixture of chrome alum, hypo, and acetate of soda.—Eds. "B.J."]

ATTEMPTS have frequently been made to compound a bath which should harden the gelatine film of negatives at the same time that it removed the silver bromide from them. Lumière and Seyewetz have shown that small additions of ordinary or chrome alum can be made to hypo solution containing a little sodium bisulphite, and that this addition imparts hardening properties to the bath. These baths, however, possess poor keeping properties, and, moreover, their action is but slight. The writer has ascertained that in the presence of sodium acetate in the fixing bath small quantities of acids, or acid salts, can be added without producing decomposition. In order to discover the properties of baths compounded on these lines, a considerable number of formulæ were tried, and the behaviour of the baths examined with regard to their hardening action and keeping properties—that is to say, freedom from decomposing action on hypo. Strips of gelatine which had been softened in cold water were treated in the different solutions.

Those subjected to baths Nos. 7, 8, and 9 became insoluble in from three to four minutes, solution 10 acted in about five minutes, and the others, Nos. 11, 12, and 13 in about eight or nine minutes. On account of the almost complete absence of precipitate in these three latter solutions, No. 13 is recommended as the best of all those examined. Its action is such that within the time necessary for the fixation of the plate a complete hardening of the gelatine takes place, and the user is therefore in the position to prevent any frilling or other variations of the plate due to differences of temperature. The speed of fixation is not appreciably reduced by the presence of the alum.

R. NAMIAS.

### RESTORING NEGATIVES OF UNEVEN DENSITY DUE TO NON-UNIFORM DRYING.

THE following note on a mishap which frequently falls to the photographic beginner is worthy of extract from the pages of our contemporary, the "Photographic Times." The method is certainly worthy of trial.

I recently made two negatives on double coated non-halation plates, and, by reason of a sudden change in the weather while the plates were drying, portions of each negatives showed much greater density than the remainder, making them totally unfit to print from. Since circumstances prevented my repeating the exposure, it was especially desirable to save the negatives, and local reduction, the only method I had ever heard recommended, seemed rather dangerous, so a means was sought which would affect the entire negative, and afford more desirable results.

Prolonged soaking in water and careful drying had no effect, nor did soaking in an acid-alum hypo bath, followed by washing and drying, make any visible difference.

The next method tried was rehalogenisation, as described in the "Photographic Times" of April, 1907, redevelopment being effected by means of a dilute pyro-soda solution, and the results were all that could be desired. The negatives, viewed by transmitted light, show perfectly uniform density, and prints from them are perfect.

Both negatives were portraits, in one case the line of demarcation lying across perfectly uniform density, and prints the sitter's cheek, in the other across a prominent portion of a white dress, so that any variation would be readily visible.

I would caution anyone trying this method against removing the plates from the developer too soon, as the action seems to be uneven in the earlier stages.

PAUL L. ANDERSON.

### THE ANNUAL INDEX TO THE "B.J."

THE publication last week of the annual index to "The British Journal of Photography" for 1907 has made us the recipients of a number of letters commenting on the comprehensive character of the index and its usefulness as a means of reference to the photographic events and progress of the past year. One of our aims in the compilation of the index being the provision of means whereby the busy man can quickly turn up a given item of news or trade intelligence, it is satisfactory to learn the view taken of it by members of the photographic trade. From some of the letters we have received we may make one or two extracts:—

Mr. A. W. W. Bartlett, of Messrs. Kodak, Ltd., writes: "It certainly seems to me to be on useful lines."

Mr. F. E. Greenwood, of Messrs. Elliott and Sons, Ltd., writes: "This will prove very useful."

Mr. Carl Hentschel, of Messrs. Carl Hentschel, Ltd., writes: "I think it should prove very useful."

Mr. J. McIntosh, Secretary of the Royal Photographic Society, writes: "The index really seems to be so full that at the moment I cannot suggest any improvement upon it."

Dr. C. E. Kenneth Mees, of Messrs. Wratten and Wainwright, Ltd., writes: "Must congratulate you not only on its completeness but on the promptitude of its appearance—before we had actually received the last number of the year! We must also take this opportunity of congratulating you on the useful 'Patents Chronology' completed in the first year of the 'Colour-Photography Supplement.'"

Mr. Charles J. Miller, of the Rotary Photographic Co., Ltd., writes: "The most thorough and complete index to a weekly publication that I have seen."

Mr. H. E. Smith, of Messrs. H. Edmund and Co., writes: "The best thing of its sort for reference in the year, and hence most acceptable."

Mr. Percy G. A. Wright, of Houghtons Ltd., writes: "The index is evidently most complete."

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—On Thursday, January 9, 1908, Mr. W. Thomas will lecture before the members of the above association upon "The Use of the Hand Camera for Newspaper Illustration," and visitors will find a hearty welcome at the meeting, which will be held at the White Swan, Tudor Street, E.C.

### FORTHCOMING EXHIBITIONS.

January 14 to 23.—Glasgow Southern Photographic Association. Entries close January 4. Sec., W. Bryce, 29, Somerville Drive, Mount Florida, Glasgow.

January 30 to February 1.—Nelson Photographic Society. Entries close January 20. Sec., Henry H. Beetham, 98, Brunswick Street, Nelson, Lancs.

February 5 to 7.—Borough of Tynemouth Photographic Society. Entries close January 25. Sec., J. R. Johnston, 29, Drummond Terrace, North Shields.

February 15 to March 7.—Scottish National Salon. Entries close January 20. Sec., Frederick W. Kay, 183, Union Street, Aberdeen.

February 19 to 20.—Royal Albert Institute, Windsor. Entries close February 14. Sec., J. W. Gooch, 9, High Street, Windsor.

February 19 to 21.—Longton and District Photographic Society. Entries close February 8. Sec., T. Mottershead, 32, Stafford Street, Longton.

February 20 to 22.—South Manchester Photographic Society. Entries close February 5. Sec., M. W. Thompstone, 2, The Grove, Whitworth Park, Manchester.

February 23 to March 2.—Birmingham Photographic Society. Entries close February 8. Sec., Lewis Lloyd, Church Road, Moseley, Birmingham.

March 4 to 5.—Canterbury Camera Club. Entries close February 22. Sec., W. E. Smith, 11, Broad Street, Canterbury.

March 4 to 7.—Ilkeston Arts Club (Photographic Section). Sec., A. Smith, 11, Graham Street, Ilkeston.

March 7 to 14.—Leicester and Leicestershire Photographic Society. Sec., Lewis Ough, F.C.S., Fernleigh, St. James's Road, Leicester.

March 7 to 21.—South London Photographic Society. Sec., E. Pady, 260, Southampton Street, Camberwell, S.E.

March 9 to 12.—Worthing Camera Club. Entries close February 29. Sec., Edmund F. H. Crouch, 11, South Street, Worthing.

March 12 to 14.—Shropshire Camera Club. Entries close March 2. Sec., W. D. Haydon, The Schools, Shrewsbury.

March 14 to 21.—Sunderland Photographic Association. Entries close March 1. Sec., W. E. Kieffer, Stirling Street, Sunderland.

March 16 to 19.—Cripplegate Photographic Society. Sec., J. G. Denyer, 15, Ostade Road, Brixton Hill, S.W.

March 18 to 21.—Nottingham Camera Club. Sec., S. W. B. Vines, 101, Sherwood Street, Nottingham.

THE LATE DR. JANSSEN.—We regret to learn of the death of Dr. Janssen, director of the Mendon Astro-Physical Observatory. Dr. Janssen, who was eighty-three years of age, two years ago received the Progress Medal of the Royal Photographic Society for his researches in astronomical photography, and in the phenomena of reversal.

A "ROTARY" ENTERTAINMENT AND PRESENTATION.—On December 21 last the directors of the Rotary Photographic Company, Ltd., gave the usual annual entertainment to their staff, which was, on this occasion, held in the newly erected hall of the Colneside Club at Ealing. The guests numbered well over 400, in the proportion of about 100 from the City office and over 300 from the local works. Among those present were Mr. Haenel (managing director), who welcomed the visitors in a very happy little speech, and Mrs. Haenel, Mr. Balfour (works manager) and Mrs. Balfour, Mr. Hones and Mr. Hill (assistant managers). The proceedings opened with a concert, in which the following took part: Herr C. K. Elderhorst and his Viennese quartette, Miss Ruby Wilson, Miss Eileen Morris, Miss Dolly Charet, who gave a humorous recitation, and Mr. Hercat, who delighted his audience with a sleight of hand and ventriloquial entertainment. At the close of this programme Mr. Balfour handed to the foremen of the various departments Christmas gifts for distribution amongst the employees of the firm in appreciation of their services, no one, from the eldest to the youngest, being overlooked. The last item on the programme was a presentation to Mr. Butler, who was leaving the firm to take up more advanced work elsewhere, from a number of his fellow employees, of a set of gold links and studs. After this the room was cleared for dancing, the proceedings terminating about midnight with "Auld Lang Syne" and the National Anthem.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents have been received between December 16 and 21, 1907:—

**DARK SLIDES.**—No. 27,845. Improvements in dark slides. Alfred Meachem, 55, Chancery Lane, London.

**PRINTING FRAMES.**—No. 27,856. Improvements in photographic printing frames. Jandus Arc Lamp and Electric Co., Ltd., and Adrian Denman Jones, Hartham Road, Holloway, London, N.

**CAMERAS.**—No. 28,185. Improvements in photographic cameras. William Booth, 3, Brown Street, Market Street, Manchester.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**PRINTING FRAMES.**—No. 19,220, 1907. This invention relates to improvements in photographic printing frames, and particularly refers to that class of frame described in a prior patent, No. 22,653, of the year 1900. In this the back of the printing frame, which is

Fig. 1.

made in two parts hinged together by two separate hinges, has the pins of such hinges projecting at the extreme ends so as to engage with vertical grooves formed in the main frame constituting the device. These grooves are lined with metallic plates secured to the frame, the object being to prevent movement of the back either in a longitudinal or lateral direction, so that when either part of the hinged back is turned up for examination of the print it can be replaced in position again without disturbing the print or negative. It has been found (in the use of separate hinges, gudgeons, and distance ferrules) that unless these are very carefully secured to the hinged back and to the hinge pin the latter will not turn about their centre accurately—that is to say, one part of the back is liable to touch the print and disturb it before its other portion gets firmly down, and consequently a bad print is the result. In addition, the use of two hinges and two hinge pins is an arrangement liable to get out of order in other ways and allow the back to shift in a lateral or longitudinal direction.

The object of the present invention is to avoid the defects referred to by providing a hinge to extend for substantially the full width of the back without the use of gudgeons and distance ferrules, a long hinge pin being employed as part of its construction, such

pin fitting in grooves as before mentioned, whilst the hinge plates, or some of them, are recessed to engage with grooves in the pin so as to secure it firmly.

Of the drawings, Fig. 1 is a back elevation of a photographic printing frame with the improvements; Fig. 2, transverse section of same on line 1, 2 of Fig. 1; whilst Fig. 3 is a longitudinal section of the hinged back showing a modified arrangement of the hinge.

Fig. 2.

In carrying out the invention, *a* represents the main frame of the device, *b* a negative, *c* the hinged back, *d* the usual spring bars for holding the back in position, *e* the metal plates provided each with a vertical groove *f* embedded and secured in the inner vertical edges of the longitudinal bars of the frame *a*, and *g* the usual staples for holding the bars *d* in position. All these parts are of similar construction to the corresponding parts in the previous patent. The present invention consists in securing to the two portions of the hinged back *c* a hinge *h* extending for substantially the full width of the back. Such hinge may be secured flush with the surface of the back as indicated in Figs. 1 and 2, by screws or

Fig. 3.

rivets *i*, or it may be embedded in the back and be secured by screws or rivets as indicated in Fig. 3. In both cases it is provided with a hinge pin *j* extending entirely through it and so that its ends project and are adapted to engage in the vertical grooves *f* of the metal plates *e*. The pins fits in these grooves both longitudinally and laterally so as to hold the back *c* firmly in position at all times and thereby prevent movement when either half of such back is lifted up to examine the print. Each half of the hinge plates may be made in one piece or in separate pieces split transversely as indicated by the broken lines *l* shown in Fig. 1. The middle sections of the hinge plates may also be dispensed with, if necessary, so long as a long hinge pin, as described, is used to connect the extreme sections of hinge plates. To hold the hinge pin firmly in position in the hinge plates it is grooved transversely at one or more points *m* and the hinge plates are dented in to engage with the grooves in the pin, as indicated at *n* in Figs. 1 and 2. Or small transverse rivets or pegs may be employed to prevent separation of the parts. John Wilkinson and Alfred Wilkinson, 6, St. Oswald Street, Manchester.

### New Trade Names.

**DOLMIT.**—No. 298,211. Chemical substances used in photography. Kodak, Ltd., 57-61, Clerkenwell Road, London, E.C., dealers in photographic materials. November 21, 1907.

**SCOTTISH NATIONAL SALON, 1908.**—The closing date for entries for the fifth annual Scottish National Salon to be held in Aberdeen is January 20, 1908, and the receiving date for pictures, February 4. Intending exhibitors can obtain full prospectus and entry form from the hon. sec., Mr. Frederick W. Kay, 183, Union Street, Aberdeen.

**A PHOTOGRAPHER'S 11,000-MILE TOUR.**—A remarkable series of photographs, the result of a tour through America, have been obtained and offered for sale by Mr. R. Banks, of 37, Fountain Street, Manchester. Mr. Banks accompanied the European Cotton Delegation on their visit to the United States to the Atlanta Cotton Convention, and during little over a month's absence from this country travelled over 11,000 miles and obtained a large series of photographs, representing life in many American and Canadian centres. A full descriptive list of the photographs has been issued by Mr. Banks.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### A Remedy for Flat Autochromes.

Owing largely to fluctuating light, the exposure problem as regards Autochromes (writes Mr. John J. Ward in "Photography") becomes quite a difficult matter to deal with, and it is very tantalising, when one has considerably increased the exposure, to find that the second, and perhaps the third, plate are almost identical result with the first. It is the more annoying, too, to spoil costly plates in this manner when the exposure is nearly correct, and one is tempted to try another plate to get a perfect result. However, by the following method I have recently been enabled to make some of these slightly under-exposed pictures into tolerably good examples:—The plate is first immersed in the following reducer, the dish being kept rocking: (a) Hypo  $\frac{1}{2}$  oz., water 10 oz. (b) Potassium ferricyanide 30 grains, water 10 oz. Equal parts of (a) and (b) are mixed for use. In this the faulty plate is reduced for five minutes or more. It is then washed for two minutes. Next it is intensified with the F and G Autochrome solutions. Finally it is treated with the H clearing solution, and fixed in the usual way with (I) the acid fixing bath.

By this considerable reduction the picture is cleared of its grey and flat appearance, and the intensifying brightens up the stronger colours. Several plates that I had "scrapped" have with this treatment yielded quite presentable pictures. In some cases the colours have at the finish of the treatment been too deep, but half a minute or so in the above reducer puts this matter right. The plate is then washed and dried.

### Control in Ozobrome.

I am convinced (writes Mr. A. H. Blake in "Photography") that of the two methods available for making ozobrome prints, one superposing the tissue on the bromide and the other making a carbon print from the bromide by transfer, leaving the bleached bromide free to be developed and used over again, the first is by far the better for control. Transferred prints do not adhere so well to their support under the action of brush and spray; and often it is hardly possible to touch them with the brush without the picture flaking off. They are also more liable to be affected by change of temperature in the water.

This is no doubt very tiresome, as it is wasteful both of tissue and of one's energy to sacrifice a print for the production of one picture, which, by the second process, would produce any number, but I only give my own experience in the matter. I must also lay stress upon the use of the extra alum solution for retaining the lighter details as given in the Ozobrome Co.'s instructions. It must be used when control is required; and it should be noted that its action does not persist long, and that if, say, an interval of a couple of hours intervenes between the pigmentation of the prints, the alum solution must be renewed. By not doing this I have been caught once or twice, and could not imagine why, after two or three prints had behaved excellently under brush manipulation, the next should peel off at a touch, until I discovered that the effect of the added alum solution does not last long. If the ozobrome control spoils a goodly number of prints, that is only a drawback that is inherent in all processes which involve personal manipulation of this kind, and are as nothing compared with the waste of prints when the gum printer is getting his effects. Workers in ozobrome will remember that there is a time, as in carbon printing, when, under the influence of the warm bath, all the superfluous pigment has been washed away, and the print stands clear and complete, and, if no control were intended, ready for immersion in cold clearing water and the drying. This is the time when the first efforts for control are to be made on the parts where the high lights are to be considerably lightened. It is as well to slip a sheet of glass under the print, so that it can be lifted flat right up to the surface of the water, for if the brush be used too much under the water, the strength of the brush stroke is not so easily ascertainable. It is not felt so easily by the finger tips, and, owing to the discoloration of the water by pigment, one cannot so easily see its effect. It will easily be understood that a little too much force soon removes the tissue altogether.

It will be found in actual practice that it is easier to transfer the print rapidly to a shallow dish of clean water of the same temperature as the developing tank. The clean, shallow water will give great advantage. The brush must be used tentatively, increasing in force and power as the colour is removed with impunity.

Great differences will be met with even in the same batch of tissue at this stage, differences for which it is not easy to account. Why should the first print be so soft and pliable that the slightest brush mark pulls the tissue off from its support, leaving spots of bare bromide print beneath, while the next print, in which all the operations have been identical, takes hand-work easily? Very delicate detail work is best not attempted at this stage; it will come later.

### The Studio Walls

I have noticed the bare, forbidding appearance of the walls in nearly every photographer's studio I have been in (writes Mr. F. M. Sutcliffe in "The Amateur Photographer"); whereas painters' studios always look the opposite—most comfortable. Is it that photographers have no invention, and cannot set themselves to work to make the walls of their workrooms pleasing to the eye? A painter will take a garret at a few shillings a week, and by papering the lower half of the walls with brown paper, and buying a few lengths of moulding and a pailful of whitewash, and by cutting a few stencils, make a most delightful room of most unpromising surroundings. The photographer will spend hundreds of pounds in velvet curtains, black and gold jardinières, palms, cocoanut trees, and velvet-covered lounges, and in the end get a most irritating room to be in. I do not mean to imply that *you* are likely to have either a fountain or a gramophone playing in your reception room, but I would venture to caution you about spending all your capital in fitting up your rooms.

### To Avoid Airbells in the Final Transfer of Carbon Prints.

I recommend the following method of making the final transfer (writes Mr. H. B. Whistler in "The Amateur Photographer") by which I have found that airbells are far less likely to be formed, provided, of course, that the instructions as to previously soaking the final support are thoroughly carried out. Place the squeegee board as level as possible, take the print (on its temporary support, which may be either flexible or opal) from the warm water, lay it on the board (face upwards, of course), and gently pour over it sufficient warm water to just cover it without running off. Be careful to see that the print, as well as the temporary support, are entirely covered by the water, at the same time breaking up any airbells should they have formed in flowing the water on. A piece of final support having been well soaked in cold water, is placed for a short time in hot water, from which it is lifted (being careful to see that no airbells are adhering to its surface) with the right hand, and one of its edges gently lowered on to a corresponding margin of the temporary support, in which position it is held firmly down by the left hand, the whole sheet then being slowly lowered across the surface of the print. This should be done with a sweeping motion, so as to drive the water in front of it as it is lowered. Squeegee into contact, starting the first stroke at about one or two inches from the left hand, and follow the direction the paper was lowered in, viz., from left to right. Hold the paper down at its right-hand edge, and squeegee the remaining one or two inches on the left-hand side, the stroke being in the opposite direction, viz., from right to left. Lay aside, quite flat, for a few minutes to set, and then hang up to dry in the usual manner.

### The Treatment of Reflections.

There is just one word of warning (says Mr. A. H. Blake, writing in "Focus") as to the technical part of the work in dealing with reflections in water or wet streets, and it is this. They require very much more exposure than at first sight one would be inclined to think. They look so light, so dainty, so full of "go" and movement that they deceive us with regard to the rapidity with which they can register themselves on the plate, and if care be not taken negatives will be under-exposed and come heavy and dark in the printing, and the movement and spontaneity, which is their chief charm, will be lost. It is difficult to get water to look really "wet";

it has a strong tendency in places to appear too solid and impenetrable a flat surface.

The caution as to under-exposure is particularly necessary in the case of street reflections—the water that reflects is very shallow—a mere film, as it were, and underneath is the dark roadway, and loss of lightness and darkness is never far to seek. The darks come too dark, for there is little light between the high houses, but the water patches catch the light and come hard and chalky.

## New Books.

"Deutscher Photographen-Kalender, Taschenbuch und Almanach, 1908." Edited by K. Schwier. Weimar: Office of "Deutschen Photographen Zeitung." Part II. M. 2.

Herr Karl Schwier, as many know, produces his annual and indispensable "Almanach" in two parts, the first containing industrial, commercial, and other particulars conveniently arranged for ready reference, and the second (now before us) comprising technical and practical information of daily use. In the volume will be found tables of weights and measures, chemical formulæ, and solubility constants, together with a very comprehensive formulary and compendium of practical information. Optical and other tables also figure in "Schwier" as in other books of a like nature, but "Schwier" is essentially a pocket book, and does not aim at the review of the year's progress to be found in Eder's Jahrbuch. We imagine even that any signs of the (happily, reduced) corpulency of the "B.J." Almanac would fill its producers with apprehension for its welfare. In its own line there is no book better edited than "Schwier."

"Photographisches Hilfsbuch für Ernste Arbeit." By Hans Schmidt. Pp. 224, 9 x 6. Berlin: Gustav Schmidt. M. 4.

We regard this as a piece of book-making rather than a contribution to photographic literature fit to rank with other really great photographic books such as are to be found in the German tongue. For all that, the author has prepared a useful work dealing with the various printing processes. Our complaint is that points which we should much like to see discussed are passed over. Thus, the chapter on the sulphide toning of bromides does not even mention any process other than the hypo-alum, although five pages are allotted to the almost obsolete uranium processes. The volume might be brought more closely in line with the actual practice of photographers.

"The Science Year-Book, 1903." Edited by Major D. F. S. Baden-Powell. London: King, Sell, and Olding. 5s. net.

Astronomical, physical, and chemical tables compose a large part of this year-book—the fourth issued—and are of a kind serviceable to the student of popular science. Similarly, the review of scientific progress during 1907 can be read with interest by those who have not had the opportunity of systematic scientific training. A glossary of recently introduced scientific terms and names is a good idea; it includes the photographic terms Celor (Goerz lens), Homocol, and Pinatype, but no others. The "Year-Book" further includes particulars of scientific societies and publications, and is also a diary with a page for each day in the year.

A CATALOGUE OF BOOKS in the library of the Royal Photographic Society has been published by the Society, and may be obtained by non-members for 5s. or by members for 2s. (postage 4½d.). The list is a volume of 193 pages, uniform in size with the Society's "Journal," and catalogues the volumes under the names of authors and also under a subject classification, an alphabetical key to which is provided. The former section calls for little comment; the latter follows the general library arrangement of collecting the books first under "Dictionaries," "General Treatises" (the largest sub-section), "Light and Optics," "Portraiture," etc., afterwards classifying works under "Negative Processes" and "Positive Processes," and sub-sections of these latter. Such classification, as those who have attempted it will admit, is not an easy matter, and the compilers of the R.P.S. catalogue appear to have adopted an intelligible and comprehensive scheme. One good feature of the catalogue is its impression on one side only of the paper, so that a blank folio faces

each printed page, and entries can be made of volumes required from time to time, which entries, we understand, are to be printed in the Society's "Journal."

## New Apparatus, &c.

"Airostyle" Improved Air Compressors. Sold by the "Airostyle" Syndicate, Ltd., 35, St. Bride Street, London, E.C.

One of the drawbacks attending the use of air-brushes where mechanical pumps are not in use seems to have been the amount of labour entailed by the use of foot pumps. To the ingenuity of Mr. Aufholz, the energetic manager of the "Airostyle" Syndicate, artists will be indebted for placing on the market two patterns of hand-pumps, intended to reduce this labour to a minimum, the neces-

The No. 2 Airostyle Air-Compressor.

sary pressure being easily kept up with the left hand. The pumps which we have been able to inspect, and one of which we illustrate, will supply a large condenser or air reservoir, enabling the worker to use on emergency two brushes, the condensers supplied with the larger of these pumps being fitted with twin taps, as shown in the cut.

The No. 1 pump is supplied with a cylinder, 18 x 8 inches, and works up to 25 to 30 lbs. air pressure. It is fitted with a 2½-inch brass pressure gauge, and costs 38s. nett.

The No. 2 size has a 23 x 9½ inch cylinder of leaded steel, and is mounted on a baseboard of solid construction, shaped so as to allow the operator to work easily with the left hand. It is fitted with a strong twin tap, and will work two "Airostyle" air-brushes. Its price is £3 10s.

Steinheil Isochromatic Parallel Glass Screens. Sold by A. E. Staley and Co., 19, Tavies Inn, Holborn Circus, London, E.C.

Users of orthochromatic plates will thank Messrs. Staley for placing at their disposal an orthochromatic light filter which is the joint product of two eminent optical establishments, the Schott Glass Works at Jena and the Munich firm of Steinheil. The new screen is made from glass coloured in the mass as the result of experiments carried out by Schott and Genossen, the makers of the famed Jena glass, whilst its optical surfacing and plano-parallelism are guaran-

teed by the well-known Steinheil firm of opticians. From an examination of one of the filters in the spectrograph and on a test chart, it is easy to see its very great superiority over previous body-coloured glass screens, the use of which has declined of late in favour of the more easily adjusted gelatine film cemented between two glass surfaces. The single glass filter can, however, be made much lighter and thinner, and lends itself more readily to easy attachment to the lens by a screw or slip-on mounting. The screens are made in two depths, one requiring about twice the exposure of the other, and the photographer's selection will be governed by the character of the plate he is using and the degree of correction at which he is aiming. The sizes in which the screens are obtained, and the prices of the latter, are as follows:—

Sizes:—  $\frac{3}{4}$  in. 1 in.  $1\frac{1}{4}$  in.  $1\frac{1}{2}$  in. 2 in.  $2\frac{1}{2}$  in.  $2\frac{3}{4}$  in. 3 in. 4 in.  
Unmounted, 6/- 7/8 9/- 9/- 10/6 12/- 15/- 18/6 22/- 25/-

Additional to which is an extra charge, according to the size of the filter, for mounting.

**BACKGROUNDS.**—Some new styles in backgrounds have been shown to us within the past few days by Messrs. F. E. Jones and Co., of 22, Gray's Inn Road, W.C., to which address photographers are invited to apply for particulars and illustrations. Some examples of ground in the style of oak panelling are a welcome variation from the usual thing, and other designs, outdoor and indoor, possess distinction, whilst the prices cannot be called exorbitant.

## New Materials.

**Time and Tank Developers.** Sold by Houghtons Ltd., 88-89, High Holborn, London, W.C.

In placing a new line of developing preparations on the market, Messrs. Houghtons emphasise their special suitability for the "stand" or "time" method of which, within the past year or two, much greater use has been made. The new introduction may equally claim the attention of both amateur and professional photographers, for its cleanness, however used—and it is, of course, just as fitted for development by the time-honoured methods of inspection as by the newer processes of "time" or "factor." A sixpenny packet of the new powders contains six cartons, each of which is dissolved in 20 oz. of water to form the "time" developer, or in three times this quantity for development by the slower "stand"

method. Messrs. Houghtons give as round figures for the time of development in the two cases, ten and thirty minutes, a recommendation which obviously may be modified by the user to suit his own requirements of density in the negative, or as may be found necessary from the character of the plate. A "hard-working" plate will do with a shorter time of development than one which builds up density slowly, but the user can easily make the necessary adjustment after one or two preliminary trials, and can then adhere to the time which gives him what he wants with the very minimum of trouble in the making up of his solution and the certainty that he is using a freshly prepared developer of a fixed composition. In addition to adhering to a time of development which he has found suitable, he has only to see that the temperature of the solution falls just about within the range of 60 deg. to 65 deg., and he

may then depend on treating a series of exposures with great regularity.

Our own experience of the developers has been very satisfactory. We found the preparation to be in a state of very fine powder, to dissolve quickly, and to be free from the slightest tendency to fog or stain. Testing a time—ten minutes—on a very soft working plate, we found that a series of hand-camera exposures made in a weak light of Christmas Day gave us negatives of good printing quality, a proof, if any were needed, of the energy of the developer. Development of plates, in batches in a tank, being now adopted by many professional photographers, who find it economical of time and labour—important items compared with cost of developer—there is good reason for drawing attention to this new powder developer, which is at once convenient, efficient, and most reasonable in price.

## CATALOGUES AND TRADE NOTICES.

**THE GAUMONT Co.,** Cecil Court, London, W.C., have issued the eighty-eighth list of new "Elge" films. A copy is obtainable post free, and will be found to contain many novel subjects.

A NEW LIST of prices for postcards from photographers' originals has just been issued by Mr. Philip G. Hunt, of 34, Paternoster Row, E.C. Mr. Hunt has a reputation to maintain for a fine average of work in P.O.P., colotype, and chromo cards, and we do not apprehend any lowering of his standard even at the very moderate prices embodied in his revised list. Those in want of any description of card may be advised to write for the new price list and for the specimen book of the firm's five leading lines.

**"THE PROFESSIONAL PHOTOGRAPHER."**—The current issue of the Kodak Company's monthly publication is of special interest from its inclusion of reproductions of the Royal groups taken by Messrs. W. and D. Downey. Among other contents of note are an illustrated description of the Kodak professional department at Clerkenwell Road and descriptions of new professional accessories and apparatus.

A PROFESSIONAL CATALOGUE.—MESSRS. JOHN J. GRIFFIN and SONS Ltd., of Kingsway, where they are just on the point of installing a professional showroom and department, have issued a special professional 64-page list which describes only accessories for the use of the professional worker, and includes a number of articles originated by the Kingsway firm. Messrs. Griffin's list (gratis and post-free) should be obtained by those who wish to have the latest introductions before them when purchasing.

**"ABEL'S PHOTOGRAPHIC WEEKLY."**—We announced in a recent issue the imminence of a photographic weekly in America to contest the field with the united "Bulletin" and "Photographer." It has now reached us in the characteristic issue of "Abel's Photographic Weekly," stated to be edited by J. C. Abel, at 18e, 23rd Street, New York City, and to be owned by A. A. E. Abel, whoever he or she may be, at the same address. Our contemporary thus gives "the reason of it." "By certain process of law my old-time creditors, during my absence from New York, secretly sold the journal with which I have been so long connected, to its competitor, 'Bulletin of Photography.' Acting on my own desire, and the counsel of my friends, I have decided to come before the public again, under the title of 'Abel's Photographic Weekly.'" Mr. J. C. Abel, in an editorial introduction, announces that he will conduct the paper in future on highly personal lines. He will drop the editorial "we," will adopt and live up to the personal "I," and he further goes on to say:—"The paper on which this is printed is not up to the standard established and maintained for so long by 'The Photographer,' but is used so that I may be able to pay my bills each week as the weekly is printed, and I am sure that my subscribers will prefer good, live, topical, up-to-date, newsy reading matter, and about men who are living, rather than nice, shiny paper bearing only articles clipped and reprinted on 'dry-as-dust' subjects. No more debt for me. I know all about it, and henceforth I propose handling nothing I cannot pay for when I get it." We wonder what Proprietor "A. A. E. Abel" is to do. Apparently he is in the enviable position of being proprietor without the inconvenience and annoyance of bills to pay, since this part of the business is to be discharged by the editor. One asks: Are things what they seem, or is visions about?

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, JANUARY 3.

Sutton Photographic Club. "Slide Making on Ilford Plates." Algernon Brooker.  
West London Photographic Society. Members' Lantern Night.

MONDAY, JANUARY 6.

Southampton Camera Club. Annual General Meeting.  
Attercliffe Photographic Society. Photographic Chemicals.  
Cleveland Camera Club. "Retouching." T. W. Windross. "Stereoscopy with a Single Camera." F. W. Pearson.  
Bradford Photographic Society. "Home-made Plates and Paper." Hubert Henry.  
Kidderminster and District Photographic Society. "Enlarging on Bromide Paper." W. Thompson.  
Catford and Forest Hill Photographic Society. "Oil Printing." M. Arbuthnot.  
Scarborough and District Photographic Society. Y.P.U. Portfolio of Prints.  
Lancaster Photographic Society. "How I Photographed a Cathedral." Rev. A. E. Miller.  
Ilford and District Photographic Society. Enlarged Negatives, &c.

TUESDAY, JANUARY 7.

Epsom and District Literary and Scientific Society. "Lantern Slides." B. J. Edwards & Co.  
Chiswick Camera Club. Rotary Carbograph Paper.  
Stafford Photographic Society. "Enlarging." W. L. Hey.  
Sheffield Photographic Society. "What Can be Done with a Hand Camera." Frederick B. Hirst.  
Hackney Photographic Society. "Black Tones on Collodion Paper." W. Foster Brigham.  
Rotherham Photographic Society. "Colour Photography." J. Tasker.  
Worthing Camera Club. "Kristal Plates, with Exhibition of Prize Slides." J. M. F. Rawlin.

WEDNESDAY, JANUARY 8.

Borough Polytechnic Photographic Society. "Bromide Printing." A. J. Bulloch.  
Coventry Photographic Club. Photography (1907) Prize Slides.  
Bristol Photographic Club. Criticism on Special Winter Competition, by the President, followed by an Exhibition of Members' Lantern Slides.  
Acton Photographic Society. Rotary Carbograph Paper.

THURSDAY, JANUARY 9.

Liverpool Amateur Photographic Association. The Prize Slides of the 1907 Competition of the Affiliated Societies.  
Longton and District Photographic Society. "Oil Printing." Rev. C. F. I. Barnwell. Focus Prize Slides. Members' Exhibition of Prints and Slides.  
Queen's Park Amateur Photographic Association. Criticism Night. S. W. Crockett.  
Chelsea and District Photographic Society. "The Optical Lantern." T. G. Coaling.  
Rugby Photographic Society. "The Principles of Composition." W. E. Tindall, R.B.A.  
L.C.C. School of Photo-Engraving and Lithography. "Press and Technical Photography." Reinhold Thiele.  
Hull Photographic Society. "Exposure." Rev. C. O. Stewart.  
Midlothian Photographic Association. Social Evening. "One Man Show." J. B. Johnstone.  
Richmond Camera Club. "Five Centuries of Church Building." Henry W. Bennett.  
Nottingham Camera Club. "Lincolnshire and Miscellaneous Slides." Thos. Wright.  
Windsor Camera Club. Rotary Specialities.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—At the meeting held on Thursday, Dec. 19, 1907 (Mr. S. H. Fry in the chair), Mr. C. H. L. Jackson lectured upon and demonstrated "Carbograph." Carbograph was, he said, a new tissue, which was prepared with bromide of silver emulsion incorporated with pigmented gelatine, and by its use direct carbon enlargements and contact prints could be easily made by artificial light. The rationale of the process was that when the tissue was exposed to light the bromide of silver was acted upon, and upon development gave a partly visible image in metallic silver. When treated with a solution of a chromate salt the silver image acted as a catalytic agent and reduced the chromate, which then tanned the gelatine in direct proportion to the amount of metallic silver deposit. The gelatine was thus rendered insoluble, whilst the silver itself was unaffected in any way. The tissue is obtainable in six colours—viz., engraving black, light green, cold sepia, warm sepia, red chalk, and photo brown, and as the colours were of various speeds, and, further, as the image was only partly visible during development, it was recommended that test exposures be made upon ordinary bromide paper, and developed in the ordinary manner. The time taken for the correct exposure should then be multiplied by the factors given in the instructions and the same developer used as was used for the test. Soft harmonious negatives full of detail were best for the process, and an iron developer should be used, as it had no tanning action upon the gelatine as had most of the more modern developers. The

print made for demonstration was of whole-plate size, and was exposed for 100 seconds at about six feet from an incandescent burner. After development, it was cleared in a 1 per cent. solution of glacial acetic acid for one minute, it was then rinsed in three changes of water and sensitised in the following bath for three minutes:—

Potass bichromate .....	384 grains.
Water .....	20 oz.
Potash alum, 10 per cent. solution.....	190 minims.

The bath keeps well, but should be filtered when returning to the bottle. It was again rinsed and then brought into contact with the transfer paper, squeezed, and laid between blotting for 10 minutes, and afterwards again developed in hot water at 100 deg. Fahr., which gave the real carbon print. After this development it was fixed in the usual 20 per cent. hypo bath for ten minutes. It was curious that the print at this stage was far darker than one would have supposed owing to the presence of the silver salt, and to obtain the brilliant red chalk of the carbon a bath of the ferricyanide and hypo reducer should be used to clear away all the silver, which should then be washed and finally dried. An orange light was all that was needed for the first development. At the same time it should be noted that the negatives for this process should be safe-edged just as for ordinary carbon work. Any single transfer paper could be used, and double transfer was not needed, except in contact printing, as by reversing the negative when enlarging the single transfer put things right.

Mr. Thomas asked if any trouble had been found from blisters, and the lecturer described the process as being absolutely free from them.

Mr. Teape asked if satisfactory enlargements had been made.

Mr. Jackson said yes, and the best results were obtained by a long soaking after the first developer up to half an hour, and before sensitising for the carbon.

Mr. Thomas asked if a brusa could be used for local work. The lecturer said it could, if used gently. The great danger would be the rubbing away of the image altogether.

Mr. Teape thought the process one of value for enlargements.

Mr. Haddon queried whether any developer could not be used if sufficient sulphite was used in compounding the same. He thought that perhaps glycin would prove of great value, as his experience was that gelatine treated with this developer remained soluble in warm water after four days' exposure. The effect of the chromate on the silver was, he said, exactly the same as in the ozotype process.

## Commercial & Legal Intelligence.

IMPERIAL DRUG STORES, LTD.—Registered December 16. Capital £600, in £1 shares. Objects: To acquire the business of wholesale and retail chemists, carried on at 171, Fulham Road, S.W., as the Imperial Drug Stores, and to carry on the business of chemists, druggists, photographers, opticians, dentists, etc. No initial public issue. Table "A" mainly applies. Registered office, 171, Fulham Road, S.W.

SUMMONS AGAINST A PORTRAIT CANVASSE.—In reference to a summons against "Watson and Co.," of Grove Road, Victoria Park, alleging that "Watson and Co." had detained a certain photograph, Mr. Cluer, at Clerkenwell, said: "I do not suppose these people read 'Truth' but this is evidently the same kind of trick exposed there. It crops up about once a year. Tanqueray and Co. is, I think, the name of the people."

When the case was called a young and good-looking Jewess appeared as the defendant.

Mr. Cluer (surprised): You are not "Watson and Co.," young lady.

The Defendant: Yes, I am.

Mr. Cluer: Are you married?—No.

Mr. Cluer: And you are trading as "Watson and Co."?—Yes.

The complainant, James Mudd, a working man, living in Robinson Road, Victoria Park, gave evidence which showed that his wife had handed to the defendant a photograph, on glass, of the witness's mother. The wife did it unknown to the husband, and was induced to do so by the defendant, who, the wife said, called and said that

Watson and Co. had opened a new studio in that neighbourhood, and in order to make their work known would give away a free copy of any photograph. Later the defendant came with an enlargement, and intimated that the framing would be 7s. 6d. The wife said she could not afford that, and then the defendant said the original would not be given up unless 2s. 6d. was paid for the proof.

The defendant went into the witness box, and said her name was Eugenia Watson. She canvassed for the photograph to enlarge. It was not true that she promised a "free" copy; she said she would submit a specimen of their work. The wife paid 6d. deposit.

Mr. Cluer: That does not bind her husband, and she did this without his authority. No doubt you thought they would not have the pluck to come into court. Give up the original, and pay 7s. costs. If all your customers, when they find themselves caught in this way, would take summonses to recover their property, they would soon stop this improper business.

**APOLLO ART ASSOCIATION.**—The "London Gazette" announces that a receiving order has been made against Frederick Vogel, photo enlarger, carrying on business under the style of the Apollo Art Association, at Jackson's Chambers, St. Peter's Street, Derby, and residing at 136, Portland Road, Nottingham.

**BRITISH PHOTO-FRAME COMPANY, LTD. (Birmingham).**—£300 10 per cent. debentures, created and dated December 6, 1907, charged on the company's property, present and future, including uncalled capital, have been registered. No trustees.

**MANSFIELD, LTD. (Photographers, Bradford and elsewhere).**—£500 5 per cent. debentures, created October 22, and dated December 10, 1907, charged on the company's undertaking and property, present capital, have been registered. No trustees.

## News and Notes.

**NORTHERN POLYTECHNIC INSTITUTE, HOLLOWAY, LONDON, N.**—Advanced class in photography is held every Tuesday from 7.30 to 9.30, from January 21 to May 1, 1908. The teacher is Mr. W. T. Wilkinson, who will deal with making enlarged negatives direct and from transparencies, retouching and working-up of enlarged negatives, and printing therefrom in carbon, gum-bichromate, and oil processes, photography in colours with Lumière autochrome plates, three-colour methods in carbon, pinatype and sinop. Orthochromatic photography will be dealt with on Saturday afternoons.

**A TREATISE ON THE CINEMATOGRAPH.**—We learn that a new work in German on the cinematograph will appear during the present month from the firm of our Dresden contemporary, "Die Photographische Industrie," the editor of which, Herr K. W. Wolf-Czapek, is its author. The new volume, which is to be entitled "Die Kinetographie," is the first German treatise on animated photography. It is to be issued at M2.50 (half-a-crown).

A CONTEMPORARY announces the publication of its thousandth number next week. No promise is made of a change in price but a number of novel features are to distinguish the issue.

**Special Announcement.**—The 2,488th number of the "B.J." will be issued on Friday next, January 10.

**PHOTOGRAPHY IN BRAZIL.**—The United States Consul-General at Rio de Janeiro has furnished his Government with a report, which has just reached London, on the trade situation as regards photography in all its branches in Brazil. He says that American cameras and accessories seem to be more prominent in the show-windows, and what advertising is done seems to be done more generally by houses having American photographic goods than by those selling the goods of any other country. But the returns of the trade do not bear out this assumption. Out of the 100,000 dollars worth of photographic appliances and accessories imported by Brazil last year, Germany sent about 37,000 dollars worth, France 32,550 dollars, Great Britain 22,010 dollars, and all other countries including the United States, about 11,500 dollars. This trade is apparently a matter of price. The superiority of American cameras for amateurs, for instance, is generally accepted, but the Americans are not offering the best goods for the least money. The general course of the photographic business seems to be similar to what it is elsewhere.

Amateur photography is not very popular, because it costs too much. Duties are high, and the original expense is high, and when to it are added high prices for supplies of every sort, it discourages the amusement. While there are many photographic concerns in Rio de Janeiro, in the entire city of something over 800,000 people there are only three houses catering to the amateur trade, and offering for sale the usual supply of local views. Galleries for portrait and similar work are fairly common and do fair work, but the best do not compare with the best in the United States. They seem to receive fair patronage and especially have calls for work at night in connection with social affairs. The concerns are not large, and the business in general would not be considered in the United States as a proper development of the industry in the community. Whether there is room for more aggressive work on the part of American photographers in Brazil is a question which only investigation by a practical photographer could dispose of with confidence. To a layman it looked as though there were an opportunity.

**THE NEW YEAR CARD** of Pirie Macdonald, photographer of men, of New York, is such a delicious piece of personal characterisation

that we cannot resist reproducing it. Mr. Macdonald, like other photographers of the States, has the genius for keeping people in a good temper when he comes on the stage. For a man who is in deadly earnest when such things as employment bureaux are under discussion, his fooling is quite admirable, and proof of his success is found in the fact that one can imagine no more welcome New Year greeting from him than the quaint caricature of himself, which is quite the Macdonald to be seen in the summer, kodak in hand, in Fleet Street and the London parks, enjoying a long vacation. Mr. Macdonald has now two New York studios, one in the city, and the other in the district answering to the London Bond Street, in both of which he photographs "men only."

**THE BOLT COURT STUDENTS' SUPPER.**—That most enjoyable function of the London County Council School of Photo-Engraving and Lithography, the annual supper and smoking concert, was held on Monday last, Mr. George Frampton, R.A., occupying the chair, supported by Messrs. A. J. Newton and Cecil Rea. The proceedings included the production of a new and original drama by Mr. F. E. Butler, entitled "The Nearer the Bone," pianoforte and violin musical selections, a recitation by Mr. Brewer, a large selection of songs by various gentlemen, a demonstration of the Black Art by Professor R. T. F. How, and a ventriloquial sketch by Mr. Val Cossy. Examples of the various kinds of work done by students in the school were on view, and the prizes for the year's work were presented to the fortunate recipients, Mr. A. J. Newton, the popular Principal of the School, receiving a most enthusiastic ovation as his share of the awards.

**FIRE AT ACTON.**—An outbreak of fire took place at Churchfield Road, Acton, last week, and resulted in loss and damage to premises occupied by Mr. Arthur Clempson, for photographic purposes.

**THE REMINGTON TYPEWRITER Co.** signalise the New Year by the issue of a most decorative wall calendar, bearing a reproduction of a painting by a New York artist of the typical Fifth Avenue girl. The Remington Co. also issue a tiny pocket diary for 1908.

To A. J. B.  
A Happy New Year

\**Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

### CONDENSED MOISTURE ON LANTERN SLIDES.

To the Editors.

Gentlemen,—What Geo. Thorne really wants is to ventilate his lantern front—that is, allow a space of about one-sixteenth of an inch between the slide carrier and the wooden front carrying the condenser. I have done this by screwing four round-headed screws into the wooden front, so that when the slide carrier is in position it is resting against the heads of the screws. If the front of the lantern is made of metal he may glue four pieces of wood on to the carriers, one at each corner.

JNO. ROBSON.

26, Scotch Street, Carlisle.

December 28, 1907.

### PORTRAITURE WITH MERCURY-VAPOUR LAMPS.

To the Editors.

Gentlemen,—I am usually a man of my word, and in the ordinary way would have adhered to my statement that I could on no account continue this debate. Since, however, Mr. Girdlestone has thought himself free from criticism he has taken what might have been a good opportunity to cavil over certain minor statements I made in my article of your issue of November 22. As I think it is only fair to you, as being responsible for the publication of that article, that I should make it clear to the readers of the "B.J." that my statements are absolutely in order, I consider it best to deal straight from the shoulder with Mr. Girdlestone's remarks. Mr. Girdlestone asks what my provincial photographer wanted with eight arc lamps. Since this is asked in his characteristic sarcastic manner it is impossible to assume that the question arises from ignorance. But, on the other hand, Mr. Girdlestone acknowledges that he is an electrician and not a photographer, it will therefore be news to him that rapidity in exposure is not all that is to be desired in artificial lighting for portraiture. The provincial photographer I mentioned knows his business, and seeks diffusion and dispersion as well as rapidity. Mr. Girdlestone says that a No. 114 Westminster lamp takes 15 ampères, which is 3 units, and not 7, as I stated in my last letter. Well, let us see what Mr. Hewitt says about it in his article of March 2, 1906 ("B.J."). "The Westminster, No. 114, lamp takes 6 to 7 units per hour," and then "in the case of the installation for the photography at the Mansion House. . . . the lamp was burning for nearly seven hours, and 75 units were used, at 3½d. per unit." Ye gods! an average of 10½ units per hour. It is impossible that such a careful writer as Mr. Hewitt should make a mistake in both instances, for he goes on to work out the cost of each exposure made. Mr. Girdlestone can scarcely condemn these facts after referring your readers to Mr. Hewitt's articles on the Westminster lamps. Then, again, Mr. Girdlestone has thought fit to have these articles reprinted, and was good enough to send me one. Surely, when advertising any article of commerce, those who are advertising it place it in as favourable a light as possible. Why did Mr. Girdlestone have these statements reprinted if they were not correct? And why refer your readers to Mr. Hewitt's articles when he is the first deliberately to refute some of the statements contained therein? Mr. Girdlestone next finds fault with my remarks about the wiring necessary with the mercury-vapour lamps, and says that it is simply nonsense to leave a distance of 2 inches between the wires in order to prevent induction. Now, Sirs, is it possible that insulators are made for that purpose and fitted in all good installations, and are not necessary? I have not stated that I have any great knowledge of electricity, but I am just a little amused at the grandiloquent manner in which Mr. Girdlestone has endeavoured to argue that I am "incompetent," and that I have no knowledge of the subject. As you know, I have confined myself to facts, which in all cases were proven, and access was given to all authorities. I must therefore assume that I have fully justified all my original statements, and would like to draw the attention of your readers to the fact that I am not financially interested in the mercury-vapour lamps, whilst Mr. Girdlestone, in fighting the cause of the Westminster lamp, is applying his zeal to commercial interests, and probably this fact accounts in some manner for his excessive personalities. Mr. Girdlestone suggests that I should

confine myself to writing from personal experience. I have done this, and the reading of it has not been altogether pleasant for Mr. Girdlestone. An expression of regret is mentioned in his letter that he should have hurt my feelings. I can assure Mr. Girdlestone that my feelings have not suffered in any way. I have only been amused at the crude efforts made to discountenance other writers as well as myself. Mr. Girdlestone seems sound in theory, but his personal application is weak. And now that I have finally washed my hands of this subject allow me to wish you and the staff of the "B.J."—readers, of course, included—a Happy New Year.

162, Ellison Street, Hebburn-on-Tyne.

GEO. R. HENDERSON.

December 20, 1907.

To the Editors.

Gentlemen,—I have read the letters of Mr. Henderson and Mr. Girdlestone with very great interest, and as I have had the mercury-vapour lamp in use for some time my reason for writing is that I cannot let Mr. Girdlestone's remark (i.e.) "Which are no doubt excellent lamps, and will take portraits if you wait long enough, etc.," pass without comment. I might add that I work slightly different from Mr. Henderson, and the exposures I give vary from ½ sec. and never more than 3 sec. for 1-1 portraits with excellent results, and amongst my photographer friends of long standing the opinion is the same as mine that the mercury-vapour lamp is the coming light for portraiture, the only slight drawback is the colour it gives one (flesh a greenish tint), but even that has its consolations, as we are not so green as the light would have us appear.

To any photographer contemplating purchasing the light I should be pleased to give them my experience and forward them a few specimens if necessary.—I am, dear Sirs, yours faithfully,

38, High Street, Worcester.

F. WHALEY.

December 21, 1907.

### ARC LIGHTS FOR PHOTOGRAPHIC PRINTING.

To the Editors.

Gentlemen,—Seeing several articles on electric lamps in recent issues of the "B.J." (mercury-vapour and arc), I have thoroughly tested several of these, and should very much like to give the readers of the "B.J." the benefit of my experience. I wrote for particulars of every photographic electric lamp I could hear of. I tested the mercury-vapour lamp, and also several arc lamps, but none of these came up to my expectations for quick printing, noiseless working, and cheapness of current with the largest power of light. The lamps in some cases did not print quick enough, and so the cost of labour increased: others had to be stopped every two or three hours to cool down, and some were flickering and breaking nearly all the time of working. I then went to the Polytechnic, Regent Street, and by kind permission of Mr. Howard Farmer, tested all the lamps there, which so thoroughly satisfied me that I placed an order with the Westminster Engineering Co. for one of their lamps. I have had the lamp about six months, and it has given every satisfaction. I have on several occasions worked the lamp continually from 9 a.m. until 2 a.m. the next morning. I think this is a great test for any lamp. The prints I get average 70 to 150 or more per hour (half-plates). The cost of current per hour works out at about 6d. in this district (alternating current at 3½d. a unit). The light I get is exceedingly steady, and electricians say it is wonderful considering the current is alternating. Enclosed find two prints, one in three minutes and the other in five minutes, which is considerably over-printed. Where time is money, the arc lamp, in my consideration, is the best on the market and cheapest in the long run as compared with mercury-vapour. Before buying any lamp I think any reader should test a "Westminster" arc, and compare results with other lamps. If any reader requires any information, or can call at my address, I shall be pleased to give him all information, show him the lamp, and allow him to test it for himself.—Yours truly,

T. E. STAGG.

The Imperial Postcard and Printing Co.,

128, Bromley Road, Catford, London, S.E.

December 30, 1907.

### THE TELEGRAPHIC TRANSMISSION OF PHOTOGRAPHS BY THE BELIN METHOD.

To the Editors.

Gentlemen,—With reference to the recent descriptions which have been given of the Belin telegraphic transmission of photographs, I beg to enclose a print which was obtained with an artificial circuit, representing a resistance of 4,000 ohms. Since this was taken, how-

ever, I have, on the 8th ult., transmitted the same subject over an actual circuit of 1,717 kilometres, running from Paris and back via Dijon, Macon, Lyons, Culle, Bordeaux, Angouleme and Poitiers.

The transmission of a plate size 13 x 18 cm., was performed in 22 minutes 3 seconds, the speed of the motor not being capable of acceleration beyond this limit. There is no doubt that the transmission can be made quicker still, and most probably in the next apparatus which I am about to construct the time may be reduced to five minutes for the transmission of a 13 x 18 print.—I am, yours very truly,  
EDOUARD BELIN.

#### THE DETERMINATION OF PINHOLE EXPOSURES.

To the Editors.

Gentlemen,—In a paper published in the "B.J." for June 22, 1906, I showed that pinhole exposures do not nearly conform to the law of inverse squares, which would demand a quadruple exposure when the plate distance is doubled. It seems to me therefore that the Watkins-Power empiric rule for pinhole exposures cannot give very precise results, seeing that it altogether ignores such deviations from the inverse square law. In the note on p. 944 of the "B.J. Almanac" the following sentence occurs: "In order to allow for the exposure in excess of the theoretical which is needed in pinhole photography." But is a general statement of this kind warranted? In the paper referred to I showed that the statement does hold when the source of illumination is a weak one, such as incandescent mantle light; but in later work not yet published I find that in bright sunlight—in the conditions under which pinholes are most frequently used—the pinhole exposure is considerably less than the theoretical when the plate is anywhere near the "best" distance, as laid down by Lord Rayleigh.

In his letter on pinhole aperture numbers in your issue of December 20, Mr. Watkins writes "of making an allowance of 50 per cent. for the 'law of error.'" What is this "law of error"? Surely the

existence of a law, properly so called, would preclude the necessity for making arbitrary allowances. Besides, the use of the term "law of error" in this connection is open to serious objection, seeing that the expression has already been allocated by general consent to physicists to an observed order in a class of phenomena with which pinhole exposures have nothing in common.—Yours faithfully,  
DOUGLAS CARNEGIE.

## Answers to Correspondents.

- \*.\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 2A, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \*.\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \*.\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO. 2A, Wellington Street, Strand, London, W.C.
- \*.\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 2A, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, &c. Two unmounted copies of each photograph must be sent with fee.

#### PHOTOGRAPHS REGISTERED:—

- G. Hynd, The Studio, High Street, King's Heath, Birmingham. Photographs of Head and Forepart of Collie Dog "Rillesley Bushman."
- J. Burlington Smith, The Studio, Darjeeling, India. Photograph, "Sunset at Kitchinjunga."

HUGH EDGSON.—We are much obliged to you for your reminder.

H. NOLAN.—Unfortunately, yes. It is one of those cases where newspaper printing is not sufficient.

TECHNICAL PHOTOGRAPHY.—Will you kindly state in your next issue what one is to understand the term "technical photography" to embrace, when used in such an instance as the advertisement of the L.C.C. for a photographer expert in this department?—W. L.

The term is commonly held to apply to all kinds of photography other than portraiture—that is to say, architectural photography, the copying of pictures or plans, the photography of furniture, lantern-slide making, and the making of prints of technical interest in contradistinction to those of, also, pictorial merit would come under the description.

HELIOS.—All we can say is that we regard all various compounds for this purpose with distrust. We advise you to try any which you intend using side by side with plain water and compare the results. It is not uncommon to find the water equally efficient.

STICKYBACK OUTFIT.—As a reader of your journal every week I would ask you the following:—What stickyback plant would you recommend, price of same, and any other particulars will be esteemed a favour? Also what light would be suitable? It is for the use of a professional photographer.—X. Y. Z.

The best advice we can give you is to refer to the lists of Jonathan Fallowfield, 146, Charing Cross Road, W.C.; the Billings Camera Works, Manchester, S.W.; or the Tress Company, Oxford Street, where you can see descriptions of the outfits. Incandescent gaslight is about the best form of lamp. The Tress Company have several patterns specially adapted for the work.

S. E.—There are no perfectly satisfactory formulæ—nothing equivalent to green carbon. You might try the carton made by the White Band Co., Croydon. The copper process is about the best for sepia tones. Formula, p. 825 of "Almanac."

STOPPING WAGES FOR HOLIDAYS.—We shall be exceedingly obliged if you will enlighten us on the following in the next number of the "Journal." Five of us are engaged in the above business myself as operator, and four young ladies in the printing and mounting. When Mr. — paid us on Saturday he deducted two days' wages from all of us, for Christmas Day and Boxing Day. On our protesting he replied that, as we were not working on those days, and they were not Sundays, we could not expect to be paid for them. We shall be glad of your opinion on the matter. I do not think our place is under the Factory Act, as there are no notices about the place.—FIVE EMPLOYEES.

The stoppages are quite illegal. The two days are statutory holidays, and you are entitled to full pay for them. You can

recover the wages for them in the County Court. The place certainly comes under the Factory Act, as there are four females employed in the work-rooms. Probably if you bring this reply to the notice of your employer he will pay up, and possibly be ashamed of his attempted shabby treatment.

**ROYAL ACADEMY.**—Kindly enlighten me in your next issue whether an artist, by exhibiting in the Royal Academy, becomes an R.A. If not, in what way could he become one?—D. KATZ.

No, decidedly not. R.A.'s—the number of whom is limited to forty—are elected by the Academicians themselves from the A.R.A.'s as vacancies occur. The only way to become a R.A. is to keep on exhibiting work, such as the members think entitle you to become an A.R.A.

**FLASHLIGHT PHOTOGRAPHS.**—I have seen photographs by flashlight of large halls and theatres crowded, looking almost sharp, near or far, as though a small diaphragm had been used; yet a large stop must have been used, or else the flashlight could not have been used; and, again, in some photographs by flashlight, the lighting seems pretty even, near or far. I am unable to get the same even in a moderate sized room, the lighting falls off very much into the distance when using the flashlight. Again, in church interiors and others, everything was sharp all over, both near and far, yet it is claimed that as large as U.S. 4 stop was used. Is that possible, as I cannot get that with my lens of the rectilinear style unless I stop down very much at the expense of the exposure? Can you explain?—C. P. (Penn, U.S.A.).

It is quite possible that the camera, in the instances to which you refer, was further from the foreground objects than on the subjects you have taken. If the buildings were large such was probably the case. Still,  $f/16$  is not an impossibly small aperture for flashlight work, and should give you sufficient definition over all the subject. Also the use of the swing back will assist in bringing the foreground into sharp focus without the need of a small aperture.

**DRYING POSTCARDS.**—I have finished a great quantity of bromide postcards (matt), and in every case they curl up with drying. I have tried various methods, but without success. As an old reader of your valuable journal will you favour me with a remedy?—ANXIOUS ONE.

Lay the cards face down on thin muslin, stretched on a frame, to dry. Messrs. Houghtons supply frames (with a special muslin) for the purpose.

**ENLARGER AS MAGIC LANTERN.**—I should be glad if you would help me. I have got a very good enlarging apparatus, very near like the sketch enclosed, but incandescent and iron back, 5in. condenser. Is it possible to convert same into a magic lantern for children's entertainments? How can it be done, and who would supply fittings and slides for same? Would it cost much for conversion? I have got other lenses that would fit if the ordinary enlarging lens would not do. I should be glad if you would help me. I am helping in the Band of Hope, and they would be delighted with it.—IGNORANT.

The lantern will answer well for a picture of small size, say, 6ft. or 10ft. diameter and if the lens is a portrait or other objective of, say,  $f/4$  aperture, otherwise the light will not be powerful enough for a brilliant picture. The only fitting necessary is the carrier, which any carpenter should be able to fix up for you, to allow of the 3½in. slides being pushed through along a groove. We should advise you to try a lantern slide on a 10ft. screen and see what result you get.

**MOUNTING IN ALBUM.**—I have a number of glazed P.O.P. prints, which I desire to mount in a book, the leaves of which are fairly thin. The prints are principally whole-plate size. Can you inform me as to the best mountant to use for this purpose?—E. C. P.

Undoubtedly the dry-mounting process, particulars of which you will find in our advertisement pages.

**FIXING BATH FOR BROMIDES.**—Will you kindly say in your valued columns if I could add a little potass. ferricyanide to my fixing bath, in order to do away with surface marks on bromides.—FRED JONES.

Certainly not; the ferricyanide will form Farmer's reducer, and will destroy the image. Better choose a paper less liable to markings and a developer specially compounded to avoid the markings. See the "B.J.," November 29.

**KALLITYPE.**—Would you kindly let me know through your journal (1) what is wrong with my method of making up Kallitype sensitiser, formula from "Ferric and Heliographic Processes"—viz.:

20 per cent. ferric oxalate .....	852 cc.
Silver nitrate .....	69 gm.
Water, to .....	1000 cc.

My first trials were completely successful, but on making up fresh sensitised a white precipitate is thrown down, about half an hour after adding silver nitrate. I have made up fresh 20 per cent. oxalate solution, and also purchased fresh sample of silver nitrate, and still the trouble occurs. Printing appears as usual, but on development I get a very poor flat image, as if there were very little or no silver present in the paper. (2) I should also like to know how long I may expect sensitiser to keep. (3) Also kindly recommend a really good book on chemistry that is likely to aid me.—ELAM D. WRATTEN.

(1) A little oxalic acid is sometimes necessary to keep the sensitiser clear. It is hardly possible that much, if any, of the silver has been thrown down, as that would mean a very copious curdy precipitate. If you will send an ounce or two of the turbid (shaken) sensitiser we could tell you better. (2) A month or more. (3) The best is "Eder's Handbuch," Band IV., Heft 13 (from W. Knapp, Halle a/S), in German. Next to it we can best refer you to Meldola's "Photographic Chemistry" (Longmans, 6s.).

**BARRY WEBSTER.**—1. We have no information on the matter. You might inquire of a Spanish paper, such as "Photos," edited by M. M. Leon Calle de Alfonso I., 19 Entresselo.

**O. A. (Chester).**—Our publishers do not undertake the sale of copyrights. In regard to your two queries, registration in England renders the photograph copyright in the countries subscribing to the Berne Convention, of which France is one. No further formalities are necessary, but as America is not a subscriber to the Berne Convention, it is necessary, to secure copyright in that country, that the negative should be made on American soil.

**X-RAY WORK.**—I am about to take up X-ray photography, and should be glad if you could advise me as to a text-book on the subject.—G. N. BIRKETT.

"Practical Radiography." By Isenthal and Ward. (Dawbarn and Ward.) 6s.

**STAMP (Redditch).**—Messrs. Christie, Manson, and Woods, 8, King Street, St. James', S.W.; Messrs. Puttick and Simpson, 47, Leicester Square, W.C.

**WET COLLODION.**—I have been trying to make a few slides by the wet collodion process, principally live subjects, but on fixing I find on some a slight deposit instead of clear glass. Is the bath too acid, or can I remove it (the stain) with a little solution of iodine? If so, what strength? Would 20 grains to loz. be too strong, and should it be followed by re-fixing?—G. P.

Without seeing one of the slides it is impossible for us to locate the cause of the fog. But it is very unlikely that it is due to the silver bath being too acid. It is more probable that it is not acid enough. If you read the series of articles on the wet collodion process, by Mr. E. W. Foxlee, that appeared in the "B.J." a few months back you will doubtless recognise the cause of your trouble. If not, send us an example. The iodine solution may be useful, but we should advise half the strength mentioned. After its use the plates should be flowed over with a very dilute solution of cyanide of potassium.

**CINEMATOGRAPH LENSES.**—1. Where could I get a good lens, and one of the largest diameter possible? 2. Is the "Darlot" cinematograph lens cylinder (2 5-64 in. diameter of tube) the largest in diameter you know of; or, if not, please mention other make?—URY.

1. It is strictly against our rule to recommend any particular maker's goods. All makers of photographic lenses supply cinematograph ones, with an aperture of about 2.2. Better get price lists from the different opticians. 2. We do not know the lens.

**HYPO-ELIMINATOR., ETC.**—1. Your article re hypo-eliminators. Do you include permanganate of potash? I have read that a few weak solutions are very rapid and effective eliminators for both prints and plates, etc., and if the colour test is a sufficient one I have in practice found that after a brief wash in plain water a few rinsings in weak solutions of the permanganate do very speedily remove the hypo, and apparently without injury to the

print, etc. 2. I make enlarged paper transparencies and negatives on thin, smooth bromide paper, as I can work them up and cannot retouch films and plates satisfactorily; but, using crayon pencils for the purpose, I find it difficult to get an even deposit of carbon (graphite?) where I want it, although I try and smooth over with a paper stump afterwards. On printing through the paper the parts worked up show up unevenly, due to the slight grain in the paper; I do not make it transparent. For small spots and straight lines it is all right, but for large patches which I want darkening in case of positives (or lightening in case of negatives—that is, when printed as a positive, using the paper negative) the result is too uneven, and the working consequently too apparent. Can you recommend something in powder form to be applied with a stump or other suitable article? Of course, I do not get quite the same sharp definition working this way as if I used plates or films for my enlarged transparencies and enlarged negatives, but as it is all so-called "pictorial" work, it is, I think, rather an advantage than otherwise. If there is any booklet on the subject will you kindly give me the reference?—**AEROGRAPH (Bray).**

1. Our remarks did not apply to permanganate. Used as you describe this is very effective, but sometimes it stains the film.  
2. Your crayon pencils are probably chalk, not graphite, and for your purpose ordinary graphite pencils would probably be much more effective. Where necessary, you could smooth down with a stump. The work requires great care, and you can only judge results by making trial prints.

**INTENSIFIER.**—1. In intensifying with the ordinary mercury-ammonia I have several times been unable to entirely blacken the plate in the ammonia. Can you give or suggest a reason for this? I may say I wash under running water for some few minutes, perhaps five, after bleaching and before putting in the ammonia, and use fairly strong ammonia bath. The fault I complain of is patches of white, presumably bleached portions of the negative, that will not blacken, even after the addition of more ammonia.  
2. Recently I was developing a very under-exposed snapshot in pyro-soda developer; the development had been going for the full time and little detail appeared, so by way of experiment I threw in the developer some strong ammonia and continued the development for some few minutes longer. I then put into hypo and did not turn up the light for fifteen or twenty minutes, when I was surprised to find my "negative" had been reversed, a positive picture being the result on the plate. Of course, there was chemical fog on the plate, but on holding the plate to the light one can trace excellent detail and contrast. Can you solve the problem of the reversal?—**REVERSAL.**

1. It is difficult to answer this definitely. Imperfect fixing or washing is probably the cause. 2. Probably due to extreme fogging. Exposure to light would have produced a reversal, and the addition of the ammonia very possibly produced a similar effect.

**MOUNT-CUTTING.**—Will you kindly give me instructions for cutting cut-out mounts, ovals, and circles for enlargements, or what tool it is done with?—**J. J.**

Space is much too limited in this column to permit of giving you such instruction as would be of really practical use. The tools most generally useful in mount-cutting are a mount-cutter's knife, a straight-edge, T-square, pair of compasses, and a three-foot rule. We should advise you to get the "Carver and Gilder's Guide." That will give you information on mount-cutting, frame-making, etc. It is published by Kent and Co., Paternoster Row, London, E.C. Its price is 2s. 6d.

**CRYSTOLEUM.**—Could you tell me the following, viz.:—1. The best place to get a good set of crystoleum painting materials from? 2. Does the glass for same cost much? 3. Is albumen paper the only paper one can use?—**D. M. M.**

1. The Alston Gallery, 52, New Bond Street, W. 2. See this firm's catalogue. 3. It is far preferable to any other, but a very thin bromide paper or P.O.P. may be used, though not with entire satisfaction, as the opaque baryta film interferes with the work and is liable to crack.

**W. SAYES.**—The most probable cause is exposure to actinic light (e.g., through an unsafe dark-room filter) during development.

**CARBON PROCESS.**—In sensitising carbon tissue I understand that a strong sensitiser reduces contrast and suits strong negatives, and a weak sensitiser increases contrast and suits weak negatives.

What is the effect of varying the time of immersion in the sensitising bath? Suppose Rotary Co.'s trichromatic films are sensitised in the same bath for one, two, and three minutes, what will be the difference in result?—**REVERSAL.**

You are quite right, a strongly sensitised tissue is most suitable for hard negatives, and a weakly sensitised one for soft ones. A longer or shorter time of immersion in the bichromate bath, to a great extent, is equivalent to employing a stronger or weaker solution. The Rotary Co.'s trichromatic films have a thinner gelatinous coating than ordinary carbon tissue, but the same holds good with them, though to a less extent, so far as the time of immersion is concerned.

**A. E. O.**—None, unless you can prove that the powder was useless for the purpose when purchased. It may have been allowed to become damp before you used it.

**W. F.**—The "Almanac" is obtainable only from retail dealers. If yours cannot supply you, you had better apply to a large London house. We will reply next week to your query.

**CHROME ALUM.**—I shall be very much obliged if you will assist me in the following matter:—I make a lot of negatives, which are subsequently stripped and reversed. A saturated solution of chrome alum is used as a hardening bath, the negative being allowed to stay in the solution for at least eight hours. The difficulty experienced is this, that with some qualities of chrome alum that we have sent us the chrome alum appears to contain an impurity of some sort, which attacks the silver image of the negative, and, besides reducing the negative in intensity, causes mottled marks and stains, rendering the negatives useless. Another example of alum from the same chemist works clean and without stains. With the alum that I suspect contains impurities I have used the simple solution (that is, I have dissolved it in water in an earthenware jar), and also have added ammonia to the solution, as recommended by Dr. Namias, I believe. The reduction of the image and production of stains occur the same in both cases. If you could tell us how to eliminate the impurity it would be of great service to us, as urgent work is often delayed by this annoyance. I perhaps ought to tell you that the negatives are not intensified or treated in any way previous to the hardening; they are well fixed and then washed for at least one hour in running water.—**IMPURITIES.**

Commercial chrome alum sometimes contains sulphuric acid, which can be removed either by shaking up the powdered chrome alum with alcohol and drawing off the latter on a filter, or can be neutralised by adding a little ammonia to the solution (until a slight precipitate is produced) and filtering.

**THE "PHOTO-SECESSION."**—A selection of fifty-eight drawings by M. Auguste Rodin will be exhibited at the Little Galleries of the "Photo-Seceession," 291, Fifth Avenue, New York, from January 2 to 21. These examples of the work of M. Rodin, which are now placed before the American public for the first time, have been specially selected for the purpose by himself and Mr. Steichen, and from their simplicity, and the fact of their being merely the notes of a sculptor for the sculpture which he is about to execute, will doubtless attract no small amount of attention and criticism.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Mr. Comley lectures this evening to the P.P.A. on "Colour Photography from a Professional Point of View." (P. 33.)

Next week's fixture in colour photography is the paper by Dr. C. E. K. Mees on "Screen-Plate Processes," at the Society of Arts on Wednesday. (P. 19.)

The winter exhibition of the Royal Academy contains among other classic works a good deal of portraiture by the old masters which may be profitably studied by photographers. Some notes on the portraits by Mr. F. C. Tilney appear on page 21.

A writer in the "Strand Magazine" has selected a particularly futile method of making a case for painted portraits as against those of the camera. (P. 19.)

At the Edinburgh Photographic Society a useful record of experience in photographing children was communicated by Mr. John Banks. (P. 22.)

Some publicity has been accorded the statement of an ex-lady-mayress to the effect that the only disagreeable moments of her year of office were spent in the cold studios of photographers. (P. 18.)

Bromoil, the oil process *via* bromide paper, was demonstrated by its originator, Mr. C. Welborne Piper, at the R.P.S. on Tuesday evening. (P. 32.)

"Photo Notes," formerly "The Bromide Monthly," is now published under the editorship of Mr. C. Welborne Piper. (P. 34.)

The effects of various methods of after-treatment of "carbograph" prints appears in the current "Photo Notes." (P. 30.)

An unexplained phenomenon in the drying of negatives with spirit—namely, the disappearance of the white deposit in water, is mentioned on page 17.

A recent paper by Mr. W. Foster Brigham gives a number of useful formulae and hints on the production of black tones on collodion P.O.P. (P. 20.)

Mr. David Powell, F.R.M.S., describes some accessories useful in the printing of small stereoscopic negatives. (P. 24.)

Mr. Douglas Carnegie, in a paper on relief illusions, explains one or two of the causes, photographic and visual, of such phenomena. (P. 25.)

Dr. W. Scheffer, in "Eder's Year-book," has given a general stereoscopic correction formula. (P. 23.)

## EX CATHEDRA.

**An Exhibition of Professional Photography.** As already referred to in our own pages, and announced in the quarterly "P.P.A. Circular," an exhibition of professional work by members of the Professional Photographers' Association will be held at the house of "The British Journal of Photography" from February 6 to March 7. The exhibition is a sequel to that held two years ago, but in the present instance the number of exhibitors will be less and the number of prints shown by each will be greater, thus permitting of a collection being brought together which better represents distinctive styles of modern professional portraiture. No charge is, of course, made to the exhibitors, and no awards are offered, or distinction made among those contributing to the exhibition. Those who have accepted the invitation to contribute prints will please notice that the last day for receiving them is January 24, and that they should be addressed to the Editors, "The British Journal of Photography," 24, Wellington Street, Strand, W.C.

## Useful Awards at Exhibitions.

The Leicestershire Photographic Society, in connection with its forthcoming exhibition, is creating a precedent in the matter of the form which awards shall take that other committees and secretaries may copy. As the first award in each class is offered, not a medal or a plaque, but a casket, which latter, judging from the reproduction in the prospectus, may be conveniently used as a receptacle for articles of value. A lady exhibitor who is fortunate enough to stand first in favour with Mr. Horsley Hinton should prize the award none the less for the fact that it provides her with another repository for jewellery or articles de toilette, while it may equally serve as a cigarette case, or to fix the locale of collar-studs and such oddments. In the case of Leicester, the casket has the respectable dimensions of 7 by 3½ by 3 inches, and is wrought in bronze. While medals are to be given at all—and experience goes to show that a provincial exhibition cannot get along without them—there seems good reason for making a move in the direction of an award which is a compromise between the plaque of alleged art qualities and the tankards, rose-bowls, and cruets of the athletic sports prize-tent.

## Methylated Spirit for Drying Negatives.

A writer in a contemporary states that opinions are divided as to the safety of drying negatives by methylated spirit, but "the objections all apply to some one else. One does not hear of really personal objections." We fear we must tell a different tale from this. Many per-

sonal objections have been brought before us, while our own experience proves that the objections have some substantial foundation. It is far safer to invest in a pint of rectified spirit, and use it economically by "drying" it with potassium carbonate after use than to trust to methylated spirit. One objection to the use of the cheaper spirit is that the results of any after-treatment of the negative, if such treatment prove to be necessary, are somewhat doubtful. A more serious objection is the appearance of a white opalescent film, apparently between the gelatine and the glass. If a negative is thoroughly soaked in methylated spirit and then dried before the fire, this film will quickly appear in the majority of cases. It is very commonly attributed to the collection of some of the foreign ingredients added to the spirit; but this idea is rendered very improbable by the fact that the film completely disappears if the negative is re-soaked in water and is then allowed to dry spontaneously. We have not seen any satisfactory explanation of the formation of this film, which seems to be one of the minor mysteries of photography, but it is certainly an effect that does not encourage us to trust to methylated spirit. It may be said that as the white film, as a rule, only appears when the negative is finally dried by heat, it is not of much consequence. Quick drying by heat is, however, one of the main advantages of using spirit. A spirit-soaked negative does not dry by any means so quickly as many suppose if heat is not used. It very soon appears dry, but this appearance is deceptive, and we have known many silver stains to be produced as the result of trusting to it.

#### Discomfort In the Studio.

An ex-lady mayoress, interviewed in a northern paper a week or two ago, declared "that the only disagreeable moments of her year of office were spent in the presence of the photographer. She had learned to abhor the word 'photographer' in big type after having paid the penalty of the office of lady mayoress by repeatedly having to shiver and pose in frightfully cold studios." There being no reason to suppose that a lady mayoress, any more than any other person of importance, should be received by the photographer without regard to the comfort provided for every sitter, the confession becomes a reflection upon photographers in the district of the lady's residence. No special emphasis need be laid on the pronouncements of a lady mayoress over and above other ladies, but it is nevertheless advisable to remind our readers, as we have done many times in the past, of the extraordinary disregard of the habitual comforts of life which appears to prevail even in studios where one would never expect it. Warmth and fresh air simultaneously in a studio are not easy to assure at all times of the winter, but they are problems in a photographer's business which it is very necessary should be solved.

\* \* \*

#### The Importance of Testing Lenses.

Of late there have been numerous complaints of lenses that prove to be of smaller aperture than they are supposed to be. We see a complaint in a contemporary of a supposed  $f/8$  lens that proved to be  $f/11$ , and we have frequently met with similar instances, including cases of  $f/8$  lenses marked at a very much larger aperture, and of long-focus lenses marked down to a short focus. The demand for very cheap extra-rapid lenses is sure to lead to a supply of this doubtful nature sooner or later, and the variety of lenses now upon the market is so great that there are far more wrongly marked lenses about than many purchasers would be likely to suppose. In some cases a simple mistake has been made, and the aperture and focal length has been upset in the process of mounting the lens

in a diaphragm shutter. In other cases, we fear, there is no mistake at all, but in any case it is very desirable that all purchasers should be on the alert and test the aperture and focal length for themselves. If an error is found, the lens should be returned at once and without hesitation to the makers. Any firm with a reputation to sustain will gladly put things right, and will, indeed, prefer to do so rather than allow wrongly marked lenses with their name upon the mount to be in use. It is needful to remember that lenses are very commonly marked in "round" figures. In the case of focal length a variation of about one-eighth of an inch, more or less, may be expected, while as regards aperture a few decimals one way or the other are of small importance. When, however, the speed is over-stated by something like 50 per cent. and the focal length understated by 20 per cent. or so, no one should have the smallest hesitation in returning his purchase.

\* \* \*

#### Photography and the Druce Case.

Photography, which has figured so prominently in the sensational Druce case, was no less to the front in the famous Tichborne suit, some five and thirty years ago. In that case the evidence of experts figured largely with regard to pictures taken by the Daguerreotype process. Amongst these witnesses were our late friend, Mr. J. Traill Taylor, the late Colonel Stuart Wortley, and others. In the present case only paper pictures have been in question. But it is quite conceivable that, considering the period, Daguerreotypes of the Duke of Portland may be in existence. Early in the present case one of the counsel made the suggestion that prior to 1850 photographs were not made on paper. The statement, of course, was absurd, since photographs on paper were produced in 1840. In the middle forties a work, "The Pencil of Nature," illustrated by photographs, was published by Fox-Talbot, copies of which are still in existence. An impression seems also to prevail that prior to the publication of the collodion process glass negatives did not exist. That, again, is a fallacy. The albumen process on glass was published in 1848, and was soon afterwards used commercially. It was a slow process, and it is very improbable that it was really used for portraiture, though, worked with certain modifications, it was an exceedingly rapid one, equalling a rapid modern dry plate. For example, in June, 1851, Talbot, at the Royal Institution, succeeded in taking a negative of some printed matter, fixed on a rapidly revolving wheel, by the momentary light from the discharge of a Leyden battery, and the lettering was quite distinct. The photographic witnesses called in the Druce case up to the present have not said anything of their personal knowledge of the state of photography earlier than about 1860. But there are, no doubt, some still living who can speak from personal experience as to what existed long prior to that date with regard to photography on both paper and glass. Previous to 1853 there were no journals devoted exclusively to photography, though the art was largely practised then. In the evidence in the Druce case retouching was referred to, but up to about 1860, or later, retouching on the negative was practically unknown, and all that kind of work was done on the prints themselves, which, when that was done, were for the most part on plain salted paper. Prints on paper, whether from calotype or collodion negatives, were mostly of the half-plate or larger size up till about 1856; the smaller sizes, such as the quarter-plate, were comparatively rarely done. It was not till about 1859 that the C.D.V. was introduced, being, at first, intended to be used as visiting cards—hence their name. They had a great vogue during the early sixties.

## PORTRAITS, PHOTOGRAPHIC AND IMPRESSIONIST.

IN the current issue of the "Strand Magazine" we find painting and photography once more set against each other like fighting-cocks. It is difficult to see what advantage can result from this eternal pitting of courteous strangers against each other's throats. Painting and photography are not adversaries, and they *should* be help-meets. The article in question is illustrated with four special colour-printed pages, each showing a photograph and what purports to be an "impressionistic" rendering of the same subject by an "artist of reputation." In the first place, such comparisons are odious. In the second place, there is nothing in the slightest degree impressionistic in the non-photographic examples, which presumably have been copied freehand from photographs supplied.

Nowadays it seems to be the proper thing never to speak of painting or sketching in those terms: the fashionable word to use is "impression"—an unfortunate term which has become a synonym for every honest word that describes the work of the professional artist.

It is not too much to say that, on the whole, and if the examples given must indeed be pronounced upon, the actual photographs are preferable to the fancy heads that are supposed to have additional artistic qualities. To grant this, however, in no way stigmatises portrait painting, or even portrait copying. If a just comparison were really desired, the fair and only way to set about it would be to arrange sitters under circumstances exactly similar to both artist and photographer, giving each full rein from beginning to end. Even then the results would prove nothing; for the risks attaching to the choice of artist would be disproportionately greater than those of the other side.

If painting and photography, as methods, have to be compared at all, it is only fair to appeal to their best exponents, past and present. That being so, Mr. Wm. Crooke himself would stand no chance against Rembrandt or Reynolds. If objection is made to this argument on the ground of commercial possibilities; if the market price or availability is to be a factor, then your clever photographer will probably give more satisfaction than your average clever hand-worker where a likeness or bald iconography is the object. The two methods are not only the poles apart, they are positively different in essence.

Suppose the case of an ardent swain in his teens so over head and heels in love with his charmer as to be at the point of writing sonnets to her eyebrow; he will naturally prize anything that gives him exactly his own dear love's eyebrow or nose-tip, and the wretchedest photograph, pictorially, will delight him. A slight enlargement of the nose-tip, should it occur as anticipated in the "Strand" article, will elude his critical faculty, especially as love is blind. Cases of sentiment of this kind, whether they are concerned with lovers or mothers, usually put a premium upon the faithful records of the camera. But where it is a case of a presentation portrait to some "society," "lodge," or civic institution, no money spent upon a photograph, be it ever so much enlarged, ever so gorgeously framed, or ever so artfully tinted, will fit it for the occasion as a smart and clever painting would be fit, even by an impecunious but talented painter who would jump at £25 for the commission.

The four artists who supply the "impressions" to this article have each been interviewed upon the subject, and their remarks are sane, clear, and logical enough to prove that they have a proper and common-sense point of view. Their names are Penrhyn Stanlaws, Gilbert Holiday, W.

Christian Symonds, and Val Havers. All the photographs are by Bassano.

The writer of the article, whose command of matters photographic may be judged from his speaking of the "Royal Photographic Salon held recently at the New Gallery," considers that no summing up of the views of the four artists is necessary, adding: "Although the argument is illustrated and enforced in various ways, it has the same conclusion—the superiority of the brush or pencil over the camera in the representation of a man or woman. Whether the conclusion is justified by the comparative examples of art and photography here given, readers of the 'Strand Magazine' must judge for themselves." But surely this is only another way of saying that the artists' views are untrustworthy. The manager of Bassano's himself admits that "there is a great deal of truth in what they say," yet the editorial stigma is thus gratuitously thrown over their opinions. As a matter of fact, the writer of the article *does* sum the matter up, and that wrongly, for the deducible conclusion from the artists' remarks is by no means that a superiority of brush or pencil over the camera exists in the representation of a man or woman. What may be deduced is that there is a difference, not a superiority. The salient point, and one that might well have been elaborated, is that the photograph gives something that one would not go to a modern painter for, and that the painter gives something which is completely impossible to the camera. The camera gives with miraculous truth, of a kind, what it seizes in the pressing of a pneumatic bulb. Whatever that is may or may not be the sum of a sitter's personality. More often than not it is about as much of the whole thing as a single picture from a biograph series is, viewed separately. The artist, on the other hand, should, if he doesn't, give the whole incident; for he sees his sitter mentally as well as physically, and probably for many days, during which a whole series of separate images build up the complete view.

Of course, these theories find no demonstration in the aimless copies of camera pictures that serve as illustrations to the article. What the artists have done with more or less success is to alter little details of costume and proportion. The results are more pictorial and less like photographs of the conventional sort. Beyond that they show nothing. It is futile to expect readers of the magazine to judge from them whether they or the others succeed best in the representation of a man or woman. It is a foregone verdict that, as portraits, the drawings are hopelessly "out of it." But what is that to do with the bombastic and chimerical question advanced?

SCREEN-PLATE COLOUR PHOTOGRAPHY.—Next Wednesday's lecture at the Society of Arts, John Street, Adelphi, London, W.C., is likely to be one of the most notable occasions of the season among evenings devoted to colour photography. Dr. C. E. Kenneth Mees will lecture on "Screen-plate Processes of Colour Photography," and will, no doubt, deal very exhaustively with this new branch of colour work of which so much has been heard within the past six months. The Society of Arts is noted for its selection of a chairman appropriate to the subject of a discourse, and it may be expected that the presidency of the meeting on this occasion will be undertaken by Sir William Abney. As regards admission, Sir Henry Trueman-Wood, the Secretary of the Society of Arts, is always ready to send a card of admission to any applicant, and the forthcoming lecture may thus be attended by all those desirous of hearing what is certain to be a most interesting lecture on a most fascinating subject.

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.—At the exhibition, to be held from March 7 to March 14, 1908, there are seven open classes, one of which is devoted to colour photography, prints and transparencies. The first award in each class will be a bronze casket, bronze medals and diplomas also being placed at the disposal of the judge. Prospectuses and full particulars can be obtained from Mr. Lewis Ough, F.C.S., "Fernleigh," St. James Road, Leicester.

## BLACK TONES ON COLLODION PAPER.

[A Paper read at the Hackney Photographic Society on Tuesday last, January 7.]

THE collodion process differs from carbon and platinotype, in which the colours obtainable are practically fixed, inasmuch as several points must be taken into consideration as bearing upon the resulting tone. The preliminary washing must be thorough, and should preferably be performed upon untripped prints, the edges being liable to peel in the future stages.

Fifteen minutes may be taken to be the minimum period allowable for the removal of the free silver. In winter or with large batches the time may beneficially be extended to as much as half an hour. These precautions are necessary to ensure the removal, not only of the unaltered silver, but also to get rid of the preserving salts used in the paper, which, whilst doing their work so efficiently, apparently influence the subsequent toning to a marked degree.

A little saturated solution of borax placed in the last washing water but three will, however, be a preventive of stains due to grease on the emulsion, and also assist the gold toning to a slight extent. This borax must on no account whatever be used if the paper is to be toned in the chloroplatinite of potassium bath alone. We must say before going further that in our experience the rich, fine blacks so much desired cannot be obtained with this single bath. Some of the single-bath papers advertised come near it, but when the prints are compared with a really good black print, they are seen to be a brown- or green-black.

To some tastes these tones are not unpleasing, and may be preferred by a few, but with the single bath process we have nothing to do in this paper. It is a mistake to imagine that the two baths mean greater cost; certainly much longer time is required to tone properly, but we are inclined to think that the double bath means a saving of material. Firstly, the gold bath is very weak, and, secondly, less platinum has to be deposited to get a good colour upon a previously gold-toned print than upon the untuned emulsion. Considering that the price of chloroplatinite has increased nearly 200 per cent. in the last six months, this is a consideration.

Washed prints are immersed a few at a time in the following gold bath:—

Gold chloride .....	2 grains.
Borax (powdered) .....	2 ounces.
Water .....	40 ounces.

If this is made up before the first washing is commenced, it will be sufficiently ripened for use when wanted. Toning will take place rapidly at first, and must be watched closely, for upon this toning the final colour *entirely depends*. Experience alone will tell the exact colour wanted in this bath, slightly varying as it does with different brands of paper. A warm chocolate is the only indication we can give. Too little toning means brown or green blacks; too long, a blue black, almost as disagreeable.

We would again point out the importance of the thorough elimination of the free silver in the preliminary washing, for if any is present the gold will tone it and give a false colour to the print. Since this colour must, within narrow limits, be a certain shade to secure the correct black, it follows that when this free silver is finally dissolved in the hypo bath, the black will be defective.

The correct colour being reached, place the prints in clear water, changing once or twice if the toning is a large one whilst the other prints are being handled.

In the above formula a definite amount of borax is given, but it is decidedly advisable to alter the proportions of borax according to the behaviour of the prints, the exact amount depending largely upon the local water. The greater the amount of borax, the less loss of detail in the high-lights is the rule, but, carried too far, the resultant prints are muddy. The borax should be added as soon as any cutting away of high-light detail is notice-

able; for this reason flat-looking prints should be placed in the bath first, so that any clearing of the high-lights will act beneficially. The latitude in the quantity of borax allowable is rather wide, so that very little observation is necessary to get good results.

One must remember, however, that the double bath process requires a very much stronger negative than the single, and the paper should be printed very dark, judging by the high-lights, and entirely neglecting any bronzing of the shadows. Whilst a gelatino-chloride negative will do for the single bath, one of carbon quality gives the best results with the two baths, and is, indeed, essential for sparkling, clean effects. If the borax is used properly, all the detail obtainable in the high-lights will be retained in the finished print.

For ten minutes after the last print has been removed from the gold bath a thorough hand washing must be given. Since platinum will only tone in an acid solution, efficient removal of the alkaline gold means quicker and more economical toning in the platinum; moreover, the free gold would combine with platinum and so waste the bath.

The dilution of the platinum stock solution is immaterial. All prints can be toned together in a weak bath, or a few at a time may be toned in a strong one; in point of view of economy of the precious metal, either method is about equal. Although the contrary would at first sight appear to be the case, the latter method is the quicker of the two, with perhaps a slight advantage of colour.

The platinum stock is:—

Chloroplatinite of potash .....	15 grains.
Phosphoric acid .....	2½ drams.
Water .....	7½ ounces.

If it is preferred to tone a batch at once, this may be diluted to 60 ounces or more. We prefer the other method, however, and fill a 15 by 12 dish to the depth of half an inch with clear water. To this we add about an ounce of stock and proceed to re-tone the prints. As soon as the bath slows down a little, more stock is added as required. This method is very economical, as then, instead of toning a few very quickly and the remainder having to soak, the bath is continually kept at convenient strength.

After toning, half of the remaining solution should be filtered off into a stock bottle to be made up to bulk with water and platinum when next required. There is no difficulty about the tone in this bath. It being impossible to over-tone, it is only necessary to avoid under-toning. The print may be judged both by reflected and transmitted light, and must not have the slightest warmth in the shadows, but look black right through.

This ends the paper on black tones, but we cannot resist calling the reader's attention to the absolute necessity of thoroughly efficient washing after the platinum bath and before fixation. The minutest trace of acid solution in the hypo will probably lead to trouble. Hand-wash for at least twenty minutes, and in the last but two waters put a few ounces of saturated solution of borax, and also in hypo. Fix in hypo 3 ounces, water 20 ounces, for at least a quarter of an hour, and again well wash. Drying before cutting out must be done upon the best chemically pure blotting, or a clean sheet, and the mounted prints must be dried quickly and thoroughly before being stacked together.

We may say that the various papers on the market differ slightly with regard to the quality of the tone obtainable, but the formula and directions suit all papers we have tried. A bad black will most probably be due to a weak negative or improper use of the gold bath. A few trials should soon prove the proper colour to get in that bath, remembering that too short toning gives brown blacks and too long blue blacks.

W. FOSTER BRIGHAM.

## PORTRAITS AT THE ROYAL ACADEMY WINTER EXHIBITION.

THE thirty-ninth exhibition of Old Masters at Burlington House is not more interesting than usual, but it is remarkable for a fine collection of Hogarths. To many who know Hogarth by doubtful reproductions of his "rakes," his "harlots," and "apprentices," he is a satirical humourist of bad draughtsman-ship and an uncommon bent towards caricature. It will be a surprise to all such to come face to face with the two large and magnificent pictures lent respectively by the Countess of Ilchester and the Earl of Normanton. The fact is that Hogarth's reputation has suffered badly at the hands of careless engravers. He was no doubt careless himself at times, when his theme absorbed him and his energies were focussed upon the spirit rather than the letter of his work. This is distinctly apparent in the three sketches for Hudibras subjects shown here. Yet that Hogarth was not only a painstaking draughtsman, but a powerful and masterly one also, the two interiors already referred to furnish memorable evidence. They are crowded with figures, and composed with the finest pictorial skill. The National Gallery Hogarths, with the exception of the redoubtable "Shrimp Girl," do not show this "grand master" side of his genius. The figures in the Earl of Normanton's "Graham Family" are of large scale, and comprise a boy, two girls, a baby, and a cat. The expressions of each, even to the cat, is a marvel of spontaneity and convincing liveliness. The boy is especially large in style and design, reminding one of the boys of Murillo and Hals, and not entirely to the advantage of those great men. The other work represents a company of distinguished persons watching a performance of a play. All the figures are portraits. "The Children of the 4th Duke of Devonshire" is another delightful group, out of doors in this case. Little Lady Cavendish is in a swing; three little male Cavendish's and a dog complete a group which again bears witness to Hogarth's mastery of action and facile designing.

The actress "Polly Peachum" is here in her proper title of Lavinia Fenton, Duchess of Bolton—a delightful portrait. Better still is the "Peg Woffington," the beautiful actress who was struck with paralysis on the stage, at the age of 37. The glorious colour of this portrait is truly Venetian. Indeed, all the pictures mentioned so far have fine colour, which, perhaps, culminates in the beautiful "Peg."

As to the social-satire works, the most irresistibly amusing is "A Woman Swearing a Child to a Respectable Citizen." The protestations of the victim to this adventitious paternity are droll in the extreme.

### Ancient and Modern Portraiture.

In the same room are a few remarkable works by Johann Zoffany, R.A., a painter of whom the man in the street is usually and excusably ignorant. To know how great and talented was Zoffany (1733-1810) the visitor need only glance at the portrait of Dr. T. Hanson. If he were to go to the New English Art Club and contemplate the most *New*, he would see amongst many things resembling this that a century has made no difference whatever to ideas in portrait painting. Dr. Hanson sits in a chair under some trees, in the shade; to the left, behind him, is a peep of landscape disclosed by a finely designed group of trees. The breadth and largeness of treatment, the simplicity of intention, the calm realism hand in hand with the finest victorial fancy, makes this quiet little gem of as much value and interest as any modern thing of similar kind with a hundred years to the good. It is because modern art so constantly harks back and imitates, that occasionally the real old things strike one as modern in appearance. Certainly we have quite come round again to the methods of Zoffany's "Lady and Gentleman";

small full-length figures in a landscape setting, a charmingly sincere work which all who are really interested in the progress of art should take note of.

### Gainsborough and Reynolds.

Mention should be made of the highly interesting Gainsborough, which is as little like the Gainsboroughs one is used to as anything could be. It is a small group of portraits of the "Pitt Family"; five persons, who stand and sit in a garden near a fine house of classical architecture. The picture is five feet by four, although the figures are small proportionately; but they are so well designed with accessories of landscape and buildings that the whole thing has an air of the grand decorative style. This is intensified by a warm, deep, and rather flat scheme of colouring.

Another group of pictures interesting to readers of the "B. J." will be the wall-full of Reynolds's in the long gallery. They may be recommended as studies in effective arrangement, particularly No. 145, "Lady Elizabeth Herbert and her Son." Dressed in white, she sits with a brown scarf over her shoulders, whilst her little naked son squats at her feet. He is a charming little figure, who reaches up his hand to caress his mother's chin. The draperies covering her lower limbs are thrown into shadow, so that the interest may be well centralised. Another delightful design is seen in the posing of "Lady Francis Scott and her Brothers." A beautiful line has been secured by making the little girl give her left hand to one of her boys. Her figure tells dark against a sky background at some parts. The work is exquisite both in planning and colour, and the losing and finding of contours is a valuable lesson to whomsoever can learn. In this latter respect, the mantle of Rembrandt sits well upon Sir Joshua's shoulders in the delightful "Miss Orby Hunter," and the treatment of contours and retiring planes may be traced in other works, of which space forbids further mention.

Some choice Romneys are also of great value educationally, that of "The Countess of Westmorland" especially, who leans with crossed arms upon a pedestal. Her dress makes a fine arrangement of folds where it is caught by the disposition of the lower limbs. The whole work is harmonious in lines and arrangement, and superior in many ways to another Romney, "Miss Rodbard," which, however, has been accorded the place of honour upon the end wall.

A portrait of Rembrandt's own son, called "Portrait of a Man" in the catalogue, is a lovely harmony in browns. The youth's handsome face, dark curls, large picturesque hat of soft black material, and the jewelled collar round his neck, are items in a luscious piece of character painting, which none the less had art for art's sake as its chief instigation.

In the first room there are four small works by unknown Flemish artists which possess the lively strength and realism for which their school is famous. These portraits are of about the scale photographers usually employ, and roughly speaking, they are about 7 by 5 inches. Nevertheless, they are frankly set down and largely conceived, in spite of their detail. A magnificent Moroni represents "Vincenzo Guarino." It is a head only, but one of those astoundingly perfect productions which excite the admiration of those few people who run after "old masters."

A parting criticism may be allowed to close this unworthy notice. No. 64, "A Cavalier Drinking," shows that its painter, Jan le Ducq, had stumbled over colour and tone values. The cavalier is a finely painted little figure in an interior, where the light catches the edges of his handsome costume with what professional photographers know, ridiculously enough, as a "Rem-

"brandt" effect. All the near planes are in rich dark tone, except the bright red leather high boots. These the artist could not bring himself to degrade by shadow deep enough for

the occasion—a curious case of a painter, evidently accomplished, being obsessed by the beauty of local colour to the point of tone-blindness.

F. C. TILNEY.

## PHOTOGRAPHING CHILDREN.

[Lecturing recently before the Edinburgh Photographic Society, Mr. John Banks dealt with many of the minor points which contribute to success in this branch of professional portraiture. The following abstract of the paper is reprinted from the current "Transactions of the Edinburgh Photographic Society."—Eds. "B.J."]

WITH regard to the mechanical part, it is, of course, necessary to have a lens working at a large aperture, quick plates and a shutter which responds readily. The one I favour is the Watson shutter with pneumatic action working behind the camera. The camera stand should also be capable of use at a low level, and with a note that the whole instrument should be easily handled we may take leave of the more mechanical part.

If any photographer was asked to name the qualities necessary to success in the photographing of children, he would probably reply, "Patience and adaptability." The first question which presents itself is, "How many of the family should be admitted into the studio?" With a baby, of course, you require somebody. I prefer to have the mother and the nurse (or aunt) on all occasions. Fathers are better kept out; they are too forceful, and force is absolutely useless when dealing photographically with children.

I also take exception to the bringing of children to be photographed who "havn't got their forenoon sleep." With fractious children, or shy children, or even stubborn children, the photographer is content to wait, but when the forces of nature are defied the case is entirely different. With regard to babies, little can be said except that they have to be taken with as much of the head shown as possible, and I prefer to cut out, if allowed a few square feet of that embroidered garment which seems so necessary to the existence of these little angels. In the case of very fractious children the exposure is often made in the surprise of the withdrawal of that invaluable article of india-rubber (used, among other things, to prevent it sucking its thumbs), and just before the squall which necessitates its replacement.

### Humouring the Baby.

Children who are just walking should have their own way for a bit; some children require to be rushed, but these are few; one generally finds that there is a faint glimmering in the child's mind, taking more shape as the child grows older, that there is something unusual going on, and you have to allow them to get over this, or at least to feel that this something is not evil; afterwards they are more pliable.

I have played with a child for about ten minutes before photographing it. In the case of shy children I have played with a toy without regard to the child till it got interested. I have let it have the whole "bag of tricks," and taken them away one by one; but the best way is not to let the child see any toys until you are quite ready. Get the camera and the background ready, a chair for the child to rest on, focus, and then attract its attention. Good pictures can also be obtained on the floor, the difficulty here being that the child always wants to get up, and there is no point of rest in this movement. The inventive faculty of the photographer, too, has to be called in. He must be able to use different methods of attraction, and be a bit of a quick-change artist at the same time; and here I may say that a photographer who is not able to get down on his knees to a child is not likely to be of much use.

### The Modern Child

Coming now to older children who have full use of their limbs, and whose intelligence is a quantity to be reckoned with. The

old story of the bird who is supposed to live inside the camera, and who will shortly appear out of the lens, is no use. I have a recollection that I once believed that myself, but the child of the period is very much wiser. If he does not ask you questions about the action of light on the bromide of silver emulsion on the plate, he may certainly come out with something you as little expect.

If I was asked whether I found boys or girls the more difficult to deal with, I am sorry to say I would have to reply, boys; and the boy who has just begun to go to school is much the worst specimen photographically. He is often too big for his size, and often does not want to be photographed. He is beginning to be "tired," a state of things which seems to occur much earlier than it used to. Anglo-Indian children, too, are difficult to manage; they are so much accustomed to service, almost from their cradles, that they are less under control; but it is, perhaps, with the child that "doesn't want to" that the photographer has his most unsuccessful and least interesting experiences. With the lively child the case is entirely different, and when the photographer is successful the pictures are very pleasing.

### Good and Bad Grouping of Children.

In the case of groups where one may find a combination of many qualities the photographer approaches his work with expectation, and if the day be a gloomy one, also with a vision of something attempted nothing done, and a dozen plates wasted. This latter does not always happen, however, for the photographer does not often care to disappoint his customer, and does his best so that some wonderful results have been got even in a bad light.

A difficult combination is baby first, then a group of the children, and last of all the family group; for once you tire a child the best thing is to ask the mother to bring it back another day.

In group work the rule of attracting the attention just at the moment of readiness applies. Children should be photographed as naturally as possible. It is a little difficult to avoid the evidence of the studio, but the evidence of the camera should be kept out of the picture. The attraction should be all from the one place, and should, as a rule, be left to the photographer. The methods of the nursery or the home do not apply. While the mother does not usually give trouble, the nurse is often more difficult to quell.

Altogether work in the studio is exceedingly interesting and instructive, and many an insight into budding human nature is obtained, and many a lesson learned by the photographer in the ordinary work of a photographic studio. It teaches one patience and tolerance, and although it may also constitute one of life's little worries, one has always the satisfaction of knowing that, after all, all earnest work contains these, and it is along these lines that success lies.

### Portraits of Children at Home and Out-of-Doors.

While the studio and the professional photographer will always be called in for the production of the portraits of children, there are many pictures which are not made, and which it is not possible to bring the camera to, simply because they are the

product of ordinary everyday or holiday life; they happen, and if the camera is not there these pictures are lost. In the back garden, in the country, or at the seaside, pictures arrange themselves, and the man with the camera at hand can secure them. I do not admire the photographs we sometimes see of the child posed front on in the garden seat with neither lighting nor anything else to distinguish it. Such "pictures" please no one but perhaps the perpetrator himself; but there are unposed pictures happening every day which no one but the man on the spot can obtain, and which the professional photographer does not and cannot attempt, except as a hobby. It is in this field that the amateur might, and does, prove himself useful. Few can paint,

but many can say when a picture is pleasing, and there is no effort beyond this latter but the securing of the picture when it offers. Posing would destroy it. It may be said that I am arguing against my own profession, but I cannot think so. We find few professionals who, if they make photography a hobby at all, take up portrait work outside their own professional sphere.

I may say in closing that the photographing of children, in the effort, the skill necessary, and in the result obtained, is to the professional one of the most interesting and pleasurable branches of his work; and to the amateur, a hobby in which he will find ample reward.

JOHN BANKS.

## A GENERALLY APPLICABLE STEREOSCOPIC CORRECTION FORMULA.

(A paper in "Eder's Jahrbuch.")

In my researches on the connection between stereoscopic taking and viewing apparatus I arrived at the following formula, given in my book "Anleitung zur Stereoskopie":—

$$\frac{o}{b} = \frac{w}{s}$$

Where

$o$  = the separation of the lenses.

$b$  = the distance of image (back focus).

$f$  = the focal length of the lenses.

$w$  = the distance between the eyes of the observer.

$s$  = the focal length of the stereoscope lenses.

It is assumed that the observer has normal vision, or that spectacles enable him to see distant objects sharply.

This correction formula applies only when the difference between the back focus  $b$  and the focus  $f$  is small, as is generally the case. The more complete formula, which applies to all cases, is

$$\frac{o}{b} = \frac{b^2}{f^2} - \frac{w}{s}$$

Hence

$$\frac{o\delta}{f^2} = \frac{w}{s} \quad \& \quad o = \frac{wf^2}{s\delta}$$

For ordinary work the factor  $\frac{6^2}{f^2}$  may be neglected. In

taking near objects, however, it cannot be disregarded. The foundation and proof of this new formula will be given elsewhere, but here I will deal only with its practical import. An example will best make this clear. Required:  $o$  the separation of the lenses. Let us assume the focus to be 60 mm.; the image distance to be 300 mm.; the focus of the lenses of the stereoscope 120 mm.; the interocular distance of the observer

65 mm. According to the formula  $o = \frac{wf^2}{b.s}$  we have  $o = \frac{65 \times 60^2}{300 \times 120}$ , therefore  $o = 6.5$  mm.

The separation of the lenses is in this case 6.5 mm. With this the distance of the object  $a = 75$  mm. according to the formula

$$a = \frac{bf}{b-f} = \frac{300 \times 60}{300 - 60} = 75 \text{ mm.}$$

According to Fig. 1

$$\frac{x}{a+b} = \frac{\frac{1}{2}a}{a}, \quad x = \frac{\frac{1}{2}a(a+b)}{a}, \quad x = \frac{\frac{1}{2}(300+75)}{2}$$

thus  $x = 16$  mm. This means that in this case the two images must partly overlap on the ground glass or the negative, if the radius of the separate pictures is more than 16 mm. When this is the case, two separate exposures must be made on two plates

one after the other. There is, of course, nothing then to prevent us from using one lens which is shifted sideways for the two operations.

The next question is the possibility of obtaining with two lenses correct stereographs for a given stereoscope. Let  $s$ , the focal length of the stereoscope lenses, be 120 mm., as above. In the following table are given the separation of the lenses and the distance between the centres of the two pictures for different enlargements and foci:  $n$  is the times of enlargement,  $f$  the focal length of the taking lens,  $o$  the separation of the same,  $m$  the separation of the centres of the two pictures on the negative. By this last phrase is meant the distance between the images of two sharply focussed points lying in the middle of the field of the object.

	$f=30$ m.	60 mm.	120 mm.
$n=1$	$\begin{cases} o=8 \text{ mm.} \\ m=16 \text{ ,,} \end{cases}$	$\begin{cases} 16 \text{ ,,} \\ 32 \text{ ,,} \end{cases}$	$\begin{cases} 32 \text{ ,,} \\ 64 \text{ ,,} \end{cases}$
$n=3$	$\begin{cases} o=4 \text{ ,,} \\ m=16 \text{ ,,} \end{cases}$	$\begin{cases} 8 \text{ ,,} \\ 32 \text{ ,,} \end{cases}$	$\begin{cases} 16 \text{ ,,} \\ 64 \text{ ,,} \end{cases}$
$n=9$	$\begin{cases} o=1.6 \text{ ,,} \\ m=16 \text{ ,,} \end{cases}$	$\begin{cases} 3.2 \text{ ,,} \\ 32 \text{ ,,} \end{cases}$	$\begin{cases} 6.4 \text{ ,,} \\ 64 \text{ ,,} \end{cases}$

From this table the remarkable fact will be noticed that for one and the same focus  $m$  is constant for all enlargements. We

have, for instance, with  $f = 120$  mm.,  $m = 64$  mm.; this means that with lenses of 120 mm.  $f$  with a distance of separation of 32 mm. we can take objects in their natural size, which will appear real in the given stereoscope. A separation of 32 mm. may be quite possible with lenses of  $f = 120$  mm. With greater enlargement the calculated separation of the lenses is so small that it is not practicable with two lenses side by side. In this case one lens must be shifted. Since  $m$  is the same for all en-

largements, assuming that a lens of the same focus is used throughout, it is necessary only to measure on the ground glass the shift of a sharply focussed point left or right from the middle, or to mark the distance on the ground glass. Further, it is noteworthy that  $m$  is directly proportional to the focus.

When we examine the curve according to which  $o$  alters as  $b$  alters, we find from the above formula

$$o = \frac{mf^2}{b \cdot s},$$

that  $o$  and  $b$  are indirectly proportional to one another. From this it is obvious that a simple mechanism can control simultaneously the back focus and separation of the lenses.

The formula here given gives the possibility of obtaining correct micro-stereographs under any desired conditions. Their use is extremely simple on the above-mentioned grounds.

Naturally, when the pictures are examined, the condition must be fulfilled that the point of intersection of the optical axis of the taking lens (or of the taking lens in the two positions) must be at the same distance from the picture plane as the optical area of the stereoscope lenses.

In conclusion I may mention that experiments by Professor Dr. Elschnig in the laboratory of Herr Hugo Hinterberger have practically confirmed my formula, the objects being taken of natural size.

The correction formula naturally only applies to the distant objects when they appear solid in consequence of parallax. Objects which are beyond this limit from the taking lens have no perceptible parallax, and the observation of such distant objects, free from parallax, takes place naturally according to the ordinary laws of perspective. If, for instance, we take stereoscopically a landscape with very long focus lenses and on a base calculated from the formula, and if we examine the stereographs with a short focus stereoscope, as required by my formula, then the objects will appear geometrically similar as regards actual corporal impressions, but will appear in other places, assuming that one actually examines the pictures at the place where they were taken.

The distance—that is to say, all lying beyond corporal perception; that is, physiologically space perception in consequence of parallax—will be seen according to the laws of ordinary perspective. In the experiment here described the distance will appear proportionately nearer and larger than in nature.

I will also add that stereograms taken with a lens separation differing from the interpupillary distance will show an enlargement or reduction of the projected images. This law runs:—The enlargement of the dimensions and the distance of the subject is equal to the quotient of the pupillary distance and the lens separation. This law has been mathematically worked out in my book.

DR. W. SCHEFFER.

## THE PREPARATION OF SMALL STEREOSCOPIC NEGATIVES FOR PRINTING.

ONE of the greatest difficulties met with by the beginner in small stereoscopic work is the adjustment of the halves of the negative for printing.

Various methods are recommended and apparatus sold for the purpose, but the chief object of these appears to be merely to facilitate the transposition of the halves of the photograph. One kind of frame on the market is devised for printing without cutting the negative. It consists of a long shaped frame with an aperture in the centre by which the light is admitted through one end of the negative to the opposite end of the transparency plate: one exposure being made for the first and another for the second half of the photograph. For cut negatives a frame is provided having rectangular recesses into which the transposed halves of the negative are dropped, the transparency plate being placed behind them and the positive made with one exposure.

In neither of these methods is provision made for the correct adjustment of the pictures on the halves. In full-sized stereoscopic photography care may be taken to arrange the two pictures on the focussing screen of the camera so that they correspond as regards horizontal and vertical lines; but with small cameras, whether used by hand or on a stand, it is practically impossible, for several reasons, to ensure both pictures being alike in these respects, and it becomes necessary that the error should be corrected by the adjustment of the halves of the negative before printing.

It is true that the before-mentioned methods of printing may give correct optical presentment in the stereoscope, but there is little satisfaction in the ability to see the photograph without strain if the picture is tilted at an angle, as is almost invariably the case by their use.

For some time I worked with a frame having a carrier with two overlapping circular recesses which permitted of the halves of the negative being rotated into similar position: but the difficulty of effecting their adjustment with even approximate exactness in the dark-room, and the liability to movement of the

two halves before the completion of the loading of the printing frame, involved the expenditure of so much time and trouble that it was with a sense of great relief that I evolved the following system of permanent adjustment.

The size of my negative is 6 by 13 cm., and I require to make transparencies for use in the Gaumont "stereodrome." I procured from Fallowfield's a quantity of the best lantern slide cover glass cut exactly to 7 by 14 cm., to serve as carriers for the negatives. In the centre of a sheet of cardboard 13 by 18 cm.

The fine ruling on the screen is omitted.

Fig. 1.

I cut a hole 73 by 143 mm., and to the back of it I firmly attached a transparent ruled focussing screen (cost ninepence) by means of Sanger-Shepherd's broad binding strips, so that the ruled lines ran true with the edges of the aperture (Fig. 1). With binding strips attached to the back of the screen, I blocked out all of the screen with the exception of two apertures which correspond exactly to those parts of the transparency which are seen in the stereoscope. To serve as guiding lines to the required separation between corresponding points in the halves of the nega-

tive I attached a narrow strip of red paper vertically down each aperture. At the top right-hand corner I made a spring clip, as shown in the diagram, and along the top I fastened two pieces of cardboard, forming spaces to act as gauges for the size of the 7 by 14 cm. glass carriers in order to ensure their fitting into the printing frame.

To mount the negative I place a glass carrier in the recess of the template, thus constructed, against the screen, so that the spring clip at the top right-hand corner sets it firmly into the bottom left-hand corner. I put a small spot of Seccotine on each corner of the glass side of each half of the negative, and, laying the halves, transposed, on the carrier, bring them into the most accurate adjustment by means of the lines on the

Fig. 2.

screen viewed through them. As the thickness of the glass of negatives frequently varies at their original extremities, which are now brought together, it is necessary to see that the halves lie flush: if they do not, they should be made level by inserting a small piece of black binding paper between the lower negative and the glass carrier. For applying the Seccotine it will be found convenient to use a large pin about three inches in length stuck firmly through a wide cork so that it will stand upright. The pin can be kept inserted in the tube of Seccotine through a small hole bored through the cap. Great care must be taken to prevent fine threads of Seccotine falling on the negative. Should for any reason the mounting be unsatisfactory, the negative can be detached from the carrier by care

fully applying a little water with a paint brush to the carrier at the edges of the negative, when the water will be drawn between the glass surfaces by capillary attraction, and the Seccotine presently dissolved without any injury to the film.

When the Seccotine is set the negative is ready for retouching: and I may mention here that it is well worth while to examine the negative in the stereoscope for faults which otherwise may escape the eye. Retouching is best done with water colour and a fine brush, with the aid of a magnifying glass. After retouching, the negative is ready for printing from at any time without further trouble.

The printing frame is the next object of attention. The box form with hinged bars is necessary, and a wooden carrier, of sufficient depth to allow a thin blackened cardboard mask as well as the glass carrier with the super-imposed negative to lie flush with its surface, is required. The mask has two apertures corresponding with those in the template, but a shade larger; and is so adjusted in the wooden carrier that when the glass carrier is set well into the bottom left-hand corner of the wooden carrier the same pictures are seen as were visible when it was in the template.

To the top side of the wooden carrier a sheet of blackened cardboard, with an aperture very slightly larger than the size of the transparency plate, namely 6 by 13 cm., is attached by a linen or tape hinge, and so arranged that, when lying down over the negative, the transparency plate, dropped into its aperture, is truly placed to receive the image from the negative. This hinged carrier must, of course, be of less thickness than the transparency plate, otherwise the latter will not receive the pressure from the back of the printing frame.

The resultant transparency will have two pictures neatly surrounded by clear margins, one of which may be utilised for the inscription of the title of the photograph.

In the foregoing I have described my own apparatus, but the details given should enable any one to construct similar apparatus for his own requirements.

If printing is effected by artificial light, it is necessary to employ a ground glass screen of, say, 12 by 15 inches in size at a distance of 6 or 8 inches from the printing frame, in order to diffuse the light: otherwise dust or minute imperfections in the glass of carrier or negative will appear as clear marks in the transparency and entirely spoil its perfection.

DAVID POWELL, F.R.M.S.

## SOME OBSERVATIONS ON ILLUSIONS IN RELIEF—VISUAL AND PHOTOGRAPHIC.

In letter V of his book on "Natural Magic," Sir David Brewster states that illusions bearing on relief were first made the subject of investigation at one of the early meetings of the Royal Society "when one of the members, in looking at a guinea through a microscope, was surprised to see the head upon the coin depressed, while other members could only see it embossed as it really was." No mention is made in this letter of those relief illusions, more or less familiar nowadays, which are produced in the case of what Von Rohr classifies as "instruments for objective use," such as the camera and the projection lantern.

Brewster states that if an intaglio cast of a medal or coin be observed subjectively through a lens or lens-system so used as to form an inverted image, the cast appears to be in relief and not in intaglio. The only explanation he offers of the illusion is as follows:—An intaglio must, of course, have its shaded portions towards the source of illumination, while in the case of a relief the shaded portions must be turned away from the source of illumination. In the inverted image of the intaglio cast formed by the lens the shaded portions are turned away from the source of illumination whose position, it is assumed, has been duly noted by the observer. Hence the illusion of relief.

But though the inversion of light and shade with respect to the known fixed position of the illuminant may be one factor in producing the illusion, it seems to me that it does not embrace the *ne plus ultra* of explanation. For I find that if an intaglio plaster cast of a medal is viewed through a large lens used as a magnifier (i.e., under such conditions that the image seen is not inverted but erect) the cast nevertheless appears to be in relief provided the observation is conducted with only one eye. When both eyes are used the cast appears in exaggerated intaglio. Indeed, the most striking method for observing the illusion is first to look with both eyes through the lens and then close one eye.

Similarly the virtual image of a hemispherical depression in a plaster slab when viewed monocularly through a magnifier appears as a hemispherical pimple rising up from the plane of the slab. Viewed binocularly through a magnifier it appears as a depression of considerably more than hemispherical magnitude. This exaggeration of intaglio observed when the virtual image is viewed binocularly can be simply explained as a result of the unusual position of the perspective point when the virtual image of an object is viewed. In such a case the perspective centre is located on the side of the object remote from the eye, with the result that nearer parts

of the object appear smaller than equal sized more distant parts (Von Rohr's "hypercentric" perspective.)

sion of relief if it were itself looked at directly with one eye. This is the case. Holding the cast of the medal some 10 inches

Since in these experiments the images formed by the magnifier did not differ from the objects in any respects save curvature and dimensions, it appeared as if the intaglio cast should suffer inver-

from the single observing eye, the deeper intaglio of the head and bust loomed up instantly in strong relief. The less deeply chased lettering of the inscription might for a moment or two appear in

its true character of intaglio, but even this suggestion of intaglio very soon changed into one of relief. When the cast was viewed binocularly under precisely the same conditions, both lettering and bust appeared instantaneously and permanently in their true character of intaglio. Since, for great distances from the observer, the difference in the characteristics of bi- and monocular vision vanishes, it follows that even if the cast is viewed with both eyes it should present the illusion of relief provided its distance from the observer is made great enough. This is the case.

Though I have sought it diligently, I have been quite unable to perceive inversion of relief in the case either of virtual erect or of real inverted images of cameos (as opposed to intaglios) whether the cameo took the form of a bronze medal, its plaster replica, or a silver coin. According to Brewster's explanation, founded solely on our appreciation of shadow effects, such an inversion should certainly take place with the real inverted images of cameos as readily as in the case of intaglios. According to the excerpt from Brewster's letter this inversion did take place with one observer when viewing a guinea through a microscope; but later on in the letter Brewster confesses "that the raised impression of a seal on wax still seemed raised to the three youngest of six persons, while the three eldest were subject to the deception." Why the inversion of intaglios should come about so readily, while cameos under like conditions of observation persistently refuse to illude some observers (myself included) is a matter which I cannot further explain than by saying that the human mind has apparently a predilection for cameo, and this, after all, is no triumph in the way of elucidation.

Attention was now directed to the appearances of cameos and intaglios when imaged objectively on the focussing screen of a camera. The objects laid on a horizontal surface of black velvet were illuminated by light from a window falling obliquely on them from above. The camera was placed with its axis vertically over the objects.

The screen image of a deep intaglio appears as a relief if the eye looks straight down upon it, but if the observer takes his stand on the side of the camera remote from the window and views the screen obliquely the image, at any rate in its less deeply incised parts (*e.g.*, the lettering of the inscription), will appear in its true character of intaglio; but the more deeply chased portions still present the illusion of relief. If, on the contrary, the image is viewed obliquely from the window side of the screen, the illusion of relief is complete in all parts of the image. Perhaps these observations regarding the direction and obliquity of the line of sight may have some share in explaining the difficulty some people apparently have in realising illusions of relief.

In these camera trials—as in the case of the previously described subjective observations—I failed to obtain any instance of complete illusion of intaglio in the case of cameo objects, with the exception sometimes of portions of the lighter relief of the inscriptions which perplexingly defied classification into relief or intaglio. The screen image taken as a whole appeared to be in its true character of cameo, whether it was viewed directly from above or obliquely with or against the direction of the light.

Photographs of the objects experimented with were taken and are here reproduced.\* In all cases the arrow-heads show the direction of the light illuminating the object. Fig. 1 is the photograph of an intaglio cast of a half-crown. If the picture be held in a horizontal plane and the observer faces the source of illumination (say, a Welsbach burner)—*i.e.*, if the conditions of illumination are just the opposite to those observed during the taking of the photograph—the illusion of relief is very strong. But if the observer turns the picture round top for bottom, the photograph of the cast appears in its true character of intaglio. If one could be assured that the photograph would always be illuminated in a definite prescribed fashion it might be advisable to photograph plaster casts of highly polished medals or coins instead of directly photographing the coins or medals themselves; this with a view to obtaining pictures free from the unpleasing variations of reflection or "glance" that usually characterise direct photographs of highly burnished metallic surfaces (see Fig. 2). In such a case the negatives would be taken on films, and the positives printed through the thickness of the film.

Fig. 2 (a photograph of a new half-crown) never presents to me the illusion of intaglio in the shield and emblazoning; however it is viewed; the print alone appears in parts to be in temporary intaglio when the picture is viewed under conditions of illumination opposite to those observed during the taking of the photograph. By temporary intaglio I mean that the appearance of intaglio is not stable and constant, but periodically vacillates backwards and forwards from intaglio to relief in an irresponsible kind of way. I should state, however, that there is evidence of personal idiosyncrasy in this case. One or two observers to whom I have submitted the photograph state that to them practically the whole of the lettering and emblazoning appears in intaglio when the picture is illuminated from a direction opposed to that of the arrow-head.

Figs. 3, 4, and 5 are photographs of a cup-shaped depression in a plaster of Paris slab; in the case of Fig. 4 the plaster was blackened and the slab placed on a white ground. If these pictures are held in a horizontal plane, with the source of illumination in front of the observer, the central depression will appear in the character of a hemispherical mound rising up out of the plane of the slab. If the sheet is now turned top for bottom or if the observer turns his back to the light the pictures give a true suggestion of hemispherical dimples in the slabs. If the pictures are held in a vertical plane and illuminated by a back light, or if the pictures in the form of lantern slides are projected on the screen, I find the great majority of people subject to the illusion that the photographs represent hemispherical reliefs.

Fig. 6 is the photograph of a bronze medal in high relief. As in the case of the half-crown picture, I cannot under any conditions of viewing obtain the slightest suggestion of illusory intaglio of the head and bust. The printed inscription (which is in much lower relief than the head) does, however, give the impression of intaglio in parts when the incident light comes from a direction opposite to that indicated by the arrow. The major portion of the inscription under these conditions of illumination presents its true character of relief.

Figs. 7 and 8 are photographs of intaglio plaster casts of the medal of Fig. 6. If either of these pictures held in horizontal plane is illuminated from directions opposite to those of the arrow-heads, the illusion of relief is very strong. If, on the other hand, light falls on the pictures in the directions of the arrow-heads, signs of intaglio appear in portions of the less deeply chased print, but the bust itself always suggests pronounced relief. This invariable illusion of relief in the bust is strange when we recall the fact mentioned above that the intaglio of the cup can be made to assume its proper appearance of intaglio under appropriate conditions of illumination.

To sum up these observations:—

1. I have never succeeded in obtaining a complete illusory inversion of the whole of a cameo of medal, cast, or coin, either by subjective (visual) or objective (photographic) means.

2. Illusory inversion of intaglio always results either in the case of monocular vision or in the case of an inverted image formed by a lens, or in the case of photographic reproductions, provided the intaglio represents such an object as a head or bust, and not merely lettering or some simple geometrical pattern.

3. In the case of lettering or geometrical design in intaglio, illusory inversion is produced by monocular vision and by photography, provided the photograph is viewed under conditions of illumination different from those which obtained during the photographic process.

DOUGLAS CARNEGIE.

**SLOW COMBUSTION FLASH POWDERS.**—A German patent has been taken out by J. Benk for preparations made up in powder or briquette form, and consisting of two constituents of different light-producing powder. A faintly actinic weak red light is first produced and gradually develops into an intense bright light. The following three mixtures are prepared:—(1) Potass permanganate, 30 per cent.; zinc, 10 per cent.; magnesium, 10 per cent.; iron, 50 per cent. (2) Nitre, 30 per cent.; iron, 30 per cent.; magnesium, 20 per cent.; and aluminium, 20 per cent. (3) Barium peroxide, 33½ per cent.; magnesium, 33½ per cent.; aluminium, 33½ per cent. The mixtures are placed in compact form in the whole composition, and provide the course of combustion above mentioned.

\* Allowance must be made for the inevitable sacrifice of delicate tones in reproductions by halftone from the original negatives.

## Photo-Mechanical Notes.

### Intaglio Printing Plates on Metal Rollers.

According to the description in a recent patent specification (No. 3,365, 1907), a process has been worked out by J. W. Ippers, of 101, Beekman Street, New York, for the production of intaglio printing surfaces having non-intersecting ridges on metal rollers. The object of the intaglio surface is to carry colour for deposition on continuous lengths of paper or cloth, the parallel ridges being to prevent the ductor (which removes the colour from the non-printing surface of the roller) from descending to the bottoms of the printing surfaces and removing a considerable portion of the colour therefrom. Reference is made by the patentee to the prior specification of Reckard (No. 23,990, 1905), which does not, it is pointed out, provide a method of preparing printing rollers with non-intersecting ridges. In carrying out the process the lithographic methods of bichromatic printing are employed, and the following is the series of operations by which the finished result is obtained:—

Fig. 1 represents a translucent glass sheet, bearing a design consisting of a flat area of opaque surface in the form of a rectangle.

Fig. 2 is a view of a lithographic stone which has photographically received an acid-resisting film upon the surface which is represented in the figure by a hollow black rectangle. The naked surface of the stone has then been etched down to a lower level, to constitute the depressed surface which is indicated by the numeral 2.

Fig. 3 is a central vertical cross section of the stone of Fig. 2.

Fig. 4 is a view of a translucent glass sheet, which has been pro-

vided with parallel black lines separated by parallel transparent lines of the same width upon one of its sides. The black lines upon the sheet of Fig. 4 are permanent, and may be produced in any of the ways in which permanent black lines are made across glass plates, to be used as screens of light in photo-mechanical printing.

Fig. 5 is a view of another lithographic stone, which has been provided photographically, through the translucent screen of Fig. 4, with narrow parallel printing surfaces, represented by the black parallel diagonal lines of that figure, and separated by narrow non-

printing surfaces represented by the white diagonal lines of that figure.

Fig. 6 is a view of a sheet of lithographic transfer paper, which has received deposits of lithographic transfer ink on its black diagonal lines, from the black diagonal printing lines upon the stone of Fig. 5. Fig. 7 is a vertical cross section of the stone of Figs. 2 and 3, with the sheet of transfer paper 6 pressed down upon the upper surface of the stone, including its black border and its depressed area 2, within that border.

Fig. 8 is a view of the stone of Figs. 2, 3, and 7 after the sheet of transfer paper 6 has been removed therefrom.

Fig. 9 is a vertical cross section of the stone of Fig. 8 with a sheet of elastic white cardboard 10, pressed down thereon, so as to receive an impression of ink therefrom.

Fig. 10 is a view of the sheet of fine white cardboard, after it has received the impression of ink, and has been removed from the stone.

### Screens for Newspaper Half-tones.

According to an abstract from the "Zentral platt für Photochemie," which has been made by Mr. S. H. Horgan, of the "Inland Printer," the Carl Richter process for producing newspaper half-tones employs two screens successively in making a single-screen negative. The one real difficulty in the production of newspaper half-tones on the present basis is the holding of detail in the shadows. So in order to overcome this fundamental difficulty when using a single screen, the Richter process utilises a single screen for the detail of the subject, and another screen effect superposed over the first, which will give the contrast, and a purity of high-lights that is unattainable when a single screen only is used. With this system it is, of course, necessary to make preliminary tests as between the two screens, so that the series of dots formed through the screen openings of the coarse screen will register exactly with the effects of the finer screen.

In carrying out the details of the process it is necessary to use two screens, the coarse one having half the number of lines that are

found on the fine screen. The effect is quite startling, for the shadows are very soft, being composed of white dots in harmony with the fine screen, and the high-lights are formed with very open dots that harmonise with the lines of the coarse screen. In the middle tones there are formed large black dots due to the coarse screen, and small black dots lying between the large ones formed by the fine screen, thus producing to the unaided eye a series of definite black cross lines in the middle tones, which are more open than the usual dots. These conditions have much to do with the printing quality of the plates, for the contrast is held up without sacrificing the detail in the shadows. The increase in interpreting power is quite marked when illustrations made with the old and the new process are placed side by side. A number of results in portraiture and commercial illustration are shown in 75-line combined with 150-line screens in contrast with the usual 75-line effects; also in 90-line ordinary and 90 and 180 combined, and 65 ordinary in contrast with combined 65 and 130 lines per inch screens. In addition, it is desirable to point out that where the two screen effects are combined—in the grays—the coarse dots coincide in position with the same number of fine dots,

and, in addition, have between them a second set of fine dots. It is, of course, understood that the first set of fine dots is lost through occupying the same space as the dots held by the coarse screen. The accompanying figure shows the relation of dots, H representing the high-lights, S the shadows, and M the middle tones. The dots of the fine screen are identified by the letter F, and those of the coarse screen by C.

### Two Pocket-Books for Photo-Engravers.

The annual pocket-book and diary issued by two of the leading houses in the process trade—Messrs. Penrose and Co. and Messrs. Hunters, Ltd.—reach our table simultaneously. Both are obtainable gratis from their respective producers. The Penrose diary includes a large number of facts and tables connected with the technical side of photo-engraving, with others on money profits and other items, which perhaps come the way of the process block maker with lesser frequency. The Hunter booklet confines itself more particularly to the chemical solutions of the engraver, but both contain formulae and hints, which are bound to be of service to the craft, as well as to photographers engaging in three-colour work.

### PHOTO-MECHANICAL PATENTS.

The following patent has been applied for:—  
**HALF-TONE SCREENS.**—No. 27,791. Improvements in screens for use in photo-mechanical engraving. Max Levy, 111, Hatton Garden, London.

**PHOTO-ENGRAVED SURFACES.**—No. 28,415. Improvements in the method, means, and process of obtaining photo-engraved surfaces. Arthur Payne, 31, Bedford Street, Strand, London.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents have been received between December 23 and 31.

**PENDANTS.**—No. 28,233. Improvements in photographic pendants. Clarence Flint, Imperial Chambers, Colmore Row, Birmingham.

**PHOTO-TELEGRAPHY.**—No. 28,277. Improvements in or pertaining to the transmission and reproduction of images by photo-telegraphy. Thomas Thorne Baker and The Pictorial Newspaper Co., Ltd., 46, Lincoln's Inn Fields, London.

**COLOUR-PHOTOGRAPHY.**—No. 28,397. Improvements in or relating to the production of photographs in colours. Herbert Sefton-Jones, 322, High Holborn, London, for Harold Nolan, Egypt.

**COLOUR-PHOTOGRAPHY.**—No. 28,398. Improvements for processes for the production of photographs in natural colours. Herbert Sefton-Jones, 322, High Holborn, London, for Harold Nolan, Egypt.

**COLOUR SCREEN-PLATES.**—No. 28,406. Improvements in or relating to plates or screens for direct colour-photography. Charles Edward Kenneth Mees and Wratten and Wainwright, Ltd., 111, Hatton Garden, London.

**CAMERAS.**—No. 28,464. Improvements in folding cameras. Magnus Niell, 88, High Holborn, London.

**TRIPDS.**—No. 28,578. Improvements in portable tripod stands. Charles John Robinson, 4, Clayton Square, Liverpool.

**CAMERAS.**—No. 28,593. Improvements in triple extension cameras. Herbert Holmes and Houghtons Ltd., 88, High Holborn, London.

**COLOUR-PHOTOGRAPHY.**—No. 28,614. Improvements in or relating to colour-photography. Arthur Schwarz, 111, Hatton Garden, London.

**STEREOSCOPIC COLOUR APPARATUS.**—No. 28,764. Apparatus for taking photographs in colours and causing them to appear stereoscopically. Louis Geisler, 40, Chancery Lane, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**COLOUR PRINTS DIRECT FROM NEGATIVES.**—No. 13,874, 1907. The invention has for its object the making of photographs in any colours, by rendering the negative unsaturatable by dyes in the dark parts, and in varying degrees of saturation over the half-tones.

After development and fixing in the usual way, the negative is immersed in a bath which renders that part which has been affected by the light in the camera unsaturatable by dyes and saturatable proportionately according to the amount of light that has fallen upon the different parts.

This bath may consist of various solutions, many chemicals having the effect in different degrees. The following are some which have the effect in varying degrees:—

(A) Uranium nitrate, 100 grs.; potassium ferricyanide, 100 grs.; water, 10 oz. (B) A 2 per cent. solution of ferric chloride with a few drops of glycerine. Immerse in A for ten minutes and follow with B for the same period.

Another bath is:—Stock solution A,  $\frac{1}{2}$  oz.; stock solution D,  $\frac{1}{2}$  oz. of Leto toning for bromides,  $\frac{1}{2}$  oz. of glycerine, 5 oz. of water. Mix A and D together and add the rest.

Another bath is:—(A) Lead nitrate, 200 grs.; potassium ferricyanide, 300 grs.; acetic acid,  $\frac{1}{2}$  drachms; glycerine a few drops. (B) Sodium sulphide,  $\frac{1}{2}$  oz.; water, 20 oz.; immerse in A first and follow with B.

Another bath is vanadium chloride, 20 gr.; potassium ferricyanide, 20 grs.; ferric oxalate, 10 grs.; ferric chloride, 10 grs.; oxalic acid,  $2\frac{1}{2}$  oz.; water, 20 oz.; glycerine, a few drops.

The negative is placed in any of the above baths until the action has fully taken place. In the case of most baths leaving the negative in them for prolonged periods does no harm, but in most cases the action should be complete in something over ten minutes. The negative is removed and washed in cold water for a few minutes, and thence transferred straight into the dye bath, or may be dried and dyed up any period later.

It should be kept in the dye bath for about ten minutes, when it is brought out and rinsed for about a minute in cold water, and then brought into contact with gelatine-coated paper, which has been previously soaked in cold water for about a minute. They may be brought into contact under water or immediately they have been taken out, when they are squeezed together and left in contact for about ten minutes, covered with a damp cloth with a piece of glass over it, to keep them moist, at the end of which time the gelatinised paper is stripped from the negative and brings the dye with it in the form of a positive in dye. The negative may then be re-dyed and used over and over again, the re-dyeing only taking about three minutes.

The latter part of the process, from the time the negative has been removed from the dye, is exactly the same as that for the impressions taken from the positive transparencies in the pinatype process.

The chief use of the invention will be for three-colour work, which will be done by bringing the gelatinised paper into contact with the three stained negatives in turn, the whole making the complete colour picture, just as the effect is obtained by the pinatype process from three positive bichromated gelatine plates.

By another method for making three-colour transparencies the negative is made and dyed as described, but instead of printing on to gelatinised paper, is placed in any reducing solution, bleaching it right away, leaving the dye in the form of a positive.

To make a three-colour transparency by this method, one of the negatives should be taken reversed in the camera through the back of the plate; another on film, so that when finished the two pictures taken on the plates may be placed face to face, and the one on film placed between them. Frank Wordsworth Donisthorpe, Hohenfels, Combe Down, Bath.

**COMBINED BATH FOR BLACK TONES.**—Professor Namias, in "Eder's Jahrbuch," recommends the following:—

1. Hypo .....	4 oz.
Water .....	10 oz.
2. Lead nitrate .....	1 oz.
Distilled water .....	10 oz.
Glacial acetic acid .....	48 minims.

Add to No. 1 enough of No. 2 to give a distinct cloudiness after well shaking, then filter.

For use take	10 oz.
Lead and hypo solution .....	10 oz.
Gold chloride .....	1 gr.

This bath tones gelatino-chloride prints very quickly, but as the solution cannot penetrate collodion so rapidly, collodion prints tone more slowly.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Cleaning Glasses of Enclosed-Arc Lamps.

The following hint for cleaning glasses of enclosed-arc lamps is given in the "Penrose Pocket Book and Diary" for 1908. Remove the white deposit with a piece of flannel charged with whiting and water, made into a paste. Then sponge off with one ounce of nitric acid, diluted with two ounces of water. Swill under the tap and polish dry with tissue paper or clean rag. The glasses should be cleaned every morning. Another way is to soak them every other night in strong potash.

### Finishing and Mounting P.O.P. Prints.

An important point to observe in drying prints on a plate (writes Mr. H. W. Bennett, in "The Photographic News") is that there should be plenty of water between the print and the plate when squeegeeing, or the print is almost certain to refuse to leave the plate when dry. The plate should be placed on the squeegeeing board, flooded with water, the print laid in position, and squeegeed into contact. If too much surface moisture be left on the back of the print after squeegeeing, it should be removed with blotting-paper or a soft towel. If a print is drained when taken from the washing water and then squeegeed to a dry ferrotype plate, sticking is almost inevitable.

### After-Treatment of "Carbograph."

The image of the finished carbograph print (says "Photo Notes") contains silver as well as pigment, and the colour is more or less effected by the presence of the black silver image. This black image can be removed, intensified or toned, hence the final result can be modified.

Farmer's reducer removes the black silver image, lightens the colour, and materially diminishes the contrast.

Intensification of the silver image darkens the colour and increases the contrast slightly.

Sulphide-toning warms the colour without very materially affecting contrast.

Iodising the silver image gives a still warmer colour and diminishes contrast slightly.

### Sulphide Toning of Bromide Prints.

It is absolutely essential (writes Mr. H. W. Bennett, in the first of a series of two articles in "The Amateur Photographer") that identical methods should be adopted in the production of all prints intended for sulphide toning, otherwise it is quite impossible to secure any desired tone with certainty. The developer that it is intended to employ must be decided upon, and its composition and degree of concentration determined, and this developer must be used invariably. In bromide work the exposures must be made to suit the developer employed; modifying the developer to compensate for irregularities in exposure is never satisfactory. It is fatal to success in toning. When the character of the negative is such that a successful print can only be obtained by modification of the developer, the tones resulting from any formula must always vary from those obtained on prints produced under normal conditions. But there should be very few negatives that require any serious departure from the standard developer. By careful adjustment of the exposure prints of uniform quality can be produced by means of the normal developer from negatives that differ widely in their degree of strength. Of course, negatives that have been very incorrectly exposed or developed will always be a source of trouble in any printing process, and bromide is no exception to this rule.

### A Suggested R.P.S. Book Club.

We would suggest (says a writer in "Focus") that the Society might considerably extend the usefulness of the library by arranging for the loan of books through the post to provincial readers. Many of these would possibly be glad to have an opportunity of studying some of the rarer photographic books included in the library. It should not be a difficult matter to devise some workable scheme, which would not only be advantageous to members not resident in London, but might prove a source of revenue to the Society.

## New Books.

"Amstutz's Handbook of Photo-Engraving." Chicago: Inland Printer Company. \$3.

We have long regarded the second edition of "Jenkins' Manual of Photo-Engraving" as the best text-book for the beginner or the man of average intelligence in photo-engraving, since it was concise, practical, and reliable. We are afraid that the third edition, which is a revision and enlargement of this manual by Mr. Amstutz and is now rightly called "Amstutz's Handbook," cannot be regarded other than as a text-book for the most advanced worker, its very comprehensiveness making it more or less dangerous to put into the hands of the beginner.

It is the first attempt at writing a text-book which shall place the processes of photo-engraving on a scientific basis with some elaboration of the principles underlying all the operations. The stages of the work are admirably classified, and the exhaustive list of materials required in every department should prove useful.

For his careful work included in the volume, and published under the "Inland Printer" under the title "Physical Characteristics of Photo-Engraving," too much praise cannot be accorded Mr. Amstutz. The measurements are most painstaking and valuable to all who can appreciate them. On the other hand, we think the book is marred by the endeavour to include almost everything that Mr. Amstutz has ever heard of in relation to new ideas in photo-engraving; the practical worker is constantly reminded that all that is new is not necessarily good, and the apparent acceptance of all sorts of claims in this volume without test is liable to mislead an inexperienced reader.

The section by Mr. Ives on the theory of half-tone and three-colour is again included, as is also the section by Mr. S. H. Horgan on practical work in three-colour, from which current English practice in many cases would differ somewhat.

An entirely new section is that relating to the office, and the advice given therein is very much needed by the employing engraver on this side at all events, though we fancy it will be a considerable time before they adopt all the mechanical time-saving devices at the end of the business recommended by Mr. Amstutz.

The L.C.C. School of Photo-Engraving in London comes in for considerable commendation, though we notice, in quoting an article by the principal from the "Process Year Book," the word "not" inserted in error when speaking of the necessity to use white paper flashing during the exposure on a severely contrasted original when employing a mezzograph screen.

There are also one or two unfortunate misprints to be recorded. For example it is stated that "benzole" and "benzine" are the same thing. "Benzine" should be "benzene."

There are a number of illustrations, which are not too well printed. Those of them which appeared in the former edition are not so good in the later impression.

The book consists of 440 pages, in closely printed type, and possesses a good index.

## New Apparatus, &c.

ZEISS AUTOCHROME ACCESSORIES.—A "Universal Palms" camera has been submitted to us by the firm of Carl Zeiss, of Margarete Street, London, W., on account of its embodying three accessories designed to facilitate the employment of the Lumière Autochrome plates in the camera. The frame of the focussing screen is provided with two grooves, one registering as usual with the sensitive surface of the plate when the latter is loaded into the slide in the usual way, and the other affording register with the emulsion film when the plate is placed glass-side to the lens, as is necessary with the Autochrome plate. The user of the camera is thus spared the trouble of removing the focussing screen each time he wishes to make a colour exposure; he can, in fact, alternate ordinary and colour exposures at no inconvenience whatever.

A carrier for the Autochrome light filter forms the second of the accessories. It is made in light metal, allows the Lumière screen to fit light-tight into it, and holds itself in the hood of the lens. With just the perfection of fit which is the result of the mechanical accuracy of the Zeiss works. In addition, a separate focussing scale is provided with red figures applying to the use of the Autochrome

date with the focussing screen reversed. This does not detract from the employment of the usual white figures for ordinary scale focussing. Particulars and prices of the above fittings may be obtained from the London branch of the Zeiss Works, Margaret Street, W.

## New Materials.

Jacoby "Mercury" Sepia Platinum Papers. Sold by Otto Scholzig, 37, Binfield Road, Clapham, London, S.W.

Samples of the platinum paper manufactured by Dr. Jacoby for the production of sepia prints by cold development, have been submitted to us by Mr. Scholzig, from whom the papers are obtainable in this country. It is explained in a memorandum that the method adopted for the paper is the incorporation of a certain proportion of a mercury salt in the sensitiser, coupled with the use of a developer to which addition of more or less of a special sepia solution can be made. Such a procedure allows of the production of a range of colours from a warm black to a very warm sepia by the ordinary direct method of development. A similar method was advocated to some considerable extent some ten years ago, when it was recommended to dose the developer with a solution of mercuric chloride, and thus obtain on ordinary "black" platinum paper prints of more or less warm colour. However, the employment of a special paper gives more elasticity to the process, as it allows the printer to graduate the warmth of his print as seems most expedient to him. It is, we suppose, common knowledge that prints which thus owe their warmth of colour to the use of mercury can be reduced and, at the same time, rendered colder in tone, by reagents such as Farmer's reducer of ferricyanide and hypo, potassium cyanide and chlorine, a difference from other sepia platinum prints in which the warmth of tone is obtained by alternative means. Yet we hold that this is not to impute impermanence to prints of the first-named order, any more than it would be in the case of bromide prints, which totally disappear in the same circumstances. While granting the greater chemical stability of the latter class of platinum print, it is nevertheless fair to accord the quality of permanence to a mercury sepia print under the ordinary conditions to which a photograph is exposed.

This, however, is a digression from our immediate object, which is to record the method followed in using the Jacoby paper and our experience of it.

The normal developer consists of potassium oxalate solution of one to seven strength, although a stronger solution may be used for softer prints. One to two parts of the sepia solution are added to four parts of the oxalate bath, and the mixture given twenty-four hours to ripen for use; or the two may be mixed at 200 deg. Fahr., and used when cold. The proportion of sepia solution is increased in order to obtain warmer tones, but the above may be taken as an average mixture, giving rich colour of moderate warmth. It is allowed to act (cold) for four or five minutes, and the prints then cleared and fixed in three successive baths of hydrochloric acid, one part in one hundred parts of water.

The papers are obtainable in eleven different grades, depending on the raw paper employed. Our experience has been with the C (medium thick, with sharp grain), and the H (white thick, smooth), which are about the average as regards surface, but a little over the mark, for small work, in substance.

"Antilumin" Dark-room Safe-Light. Sold by A. G. Clarkson, Colchester.

Mr. Clarkson, of Colchester, purveyor of many useful specialties for the profession and the amateur, sends us a sample of this flexible substitute for red glass, which is obtainable, wholesale only, from him. The material is a thin paper rendered translucent, and, at the same time, damp-resistant, by an application with varnish. It is to be attached to glass by painting one of its surfaces, and also that of the glass, with a weak (1 in 80) solution of gelatine, and squeegeeing into even contact. It can be applied in this manner to existing windows, or mounted on glass for use in dark-room lamps. In the latter case its semi-transparent substance diffuses the light and provides a comfortable illumination for "dark-room" work. As regards its safety, we have tested the material in front of an 8-candle power lamp, and found it a safe light for the develop-

ment of orthochromatic plates—that is to say, with the usual precautions. No safe-light, as the recent measurements of Mees and Baker ("B.J. Almanac," 1908, page 587) have shown, is perfectly safe, but filters differ very greatly in their illumination for a sufficient degree of safety, and in this respect Antilumin stands well amongst available materials. Moreover, so far as our experience of it has gone, it is not liable to crack and buckle, and may be employed in lamps where the filter is apt to get uncomfortably warm. It is certainly a preparation which may be recommended for its specific purpose.

"ENSIGN" ROYAL ART MOUNTING BOARDS.—A year or two ago it was difficult to get beautiful mounting boards such as these of Messrs. Houghtons Ltd., now issued in sheets 25 x 20 inches, at 2s. 6d. per dozen in a light substance, and 6s. per dozen thick. There are nine tints to select from, and among the lot not one which is a useless colour. Such a well-selected stock of boards ought to be most useful to any photographer in producing something out of the ordinary, whilst the mounter of portraits in folders and the like will not need our recommendation to take advantage of Messrs. Houghtons' offer to send specimen books of the boards to bona-fide readers of the "B.J." It is not much good our attempting descriptions of the boards; they should be seen.

"CIRCROID" CHROMIUM INTENSIFIER. Messrs. Houghtons Ltd. have issued this reliable intensifier in the convenient compressed tablet form designated "Circroid" by them. The shilling packet contains one tube of the bleaching compound and two of the constituents of the re-developer. We found it to act quite satisfactorily on a number of negatives, whilst as an intensifier of lantern slides the chromium preparation is about the only one which is clean, and, at the same time, permanent in its results. Another useful property of the intensifier, which we found possessed by the "Circroid" preparation, is the fine rich black given to bromides which are not all they should be.

## CATALOGUES AND TRADE NOTICES.

"WINTER WORK WITH A KODAK."—A 32-page illustrated booklet of the branches of photography which may be followed during the winter months, has been issued by the Kodak Company, and is obtainable, post free, on application to Clerkenwell Road, E.C.; whence, also, we believe we are right in saying, dealers may obtain supplies for their counters. The booklet emphasises, with many excel-

lent reproductions, the facilities of photography, indoors and out, with a Kodak, despite the inclemency of the season. It deals with landscape and figure work, portraiture, flashlight, enlarging, and lantern slide making, and specifies suitable apparatus for these purposes. Decidedly a publication to maintain interest in the camera in the winter.

THE CLASSES AT THE CRIPPLEGATE INSTITUTE, Golden Lane, City, under instruction of Mr. John H. Gear, will commence a new session on Wednesday next, January 15. There will be a Practical Class specially for oil-pigment printing, Autochrome lantern-slides and enlarged negatives, each Wednesday at 6.30 p.m.; also a general lecture course at eight o'clock. These classes are arranged to be beneficial to those engaged professionally, as well as to the amateur, and special assistance will be given to those desirous of sitting for the diplomas awarded by the London Chamber of Commerce and The City and Guilds of London Institute.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, JANUARY 10.

Sutton Photographic Club. "Failures and Remedies"

Borough of Tynemouth Photographic Society. Rotary Carbohydrate Paper.  
Blenheim Club. "Playing Cards; Historical and Curious." Alfred Whitman.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, January 7, the President, Mr. J. C. S. Mummery in the chair

A demonstration of the "bromoil" process of oil printing was given by Mr. C. Welborne Piper, to whom the origination of the process was due. Mr. Piper explained the operations to which the bromide print was submitted in preparing its surface to take an image in pigment. The print was first bleached in a solution composed as follows:—

Ozobrome stock solution .....	4 parts.
10 per cent. potash alum solution .....	4 parts.
10 per cent. citric acid solution .....	1 part.
Water, to make .....	20 parts.

This was half the strength of the bleaching bath originally recommended by Mr. Piper, as it was found that the stronger solution was liable to blister some brands of bromide paper. The bleached print was rinsed for a moment under the tap and then immersed in 5 per cent. sulphuric acid until the bichromate stain disappeared and only a faint, whitish image remained. It was then fixed for one or two minutes, washed, blotted off, and laid on damp blotting paper for pigmentation.

The various stages of this process were demonstrated in a number of instances by Mr. Piper.

In reply to a number of questions, the lecturer said that he preferred to use a palette of Bristol board for the pigment, as the card surface caused the pigment to dry rapidly and to quickly reach a more tacky stage, in which it was of service in obtaining greater contrasts in the pigment prints.

Asked as to the respective merits of ordinary, platino-matt, and

glossy bromide paper, Mr. Piper said that usually platino-matt and the ordinary surface were equally suitable, but that depended to some extent on the make of the paper. Glossy paper was not so suitable, and rough papers were difficult to work. As regards light papers, some of them might be used whilst others he found unworkable.

One necessary precaution was to avoid over-working the acid bath. It might be taken as a safe rule that a half-dishful of acid bath should not be used for more than six prints of its own size, otherwise the prints were liable to take the pigment all over.

He found the black brushes sold for the Rawlins oil process to be the most suitable, hog-hair brushes he found too stiff. To a certain extent the pigmented print could be de-pigmented with dry brush.

In reply to Mr. Manly, the lecturer said he had tried other acid baths, such as hydrochloric and acetic, but he found the sulphuric acid the best.

A short discussion in which Messrs. E. T. Holding, W. Thomas, John H. Gear, C. H. Hewitt, E. C. Morgan, and others took part followed the demonstration.

It was announced that the next monthly demonstration at the Society will be that of oil printing by Mr. John H. Gear.

**SOUTH LONDON PHOTOGRAPHIC SOCIETY.**—Mr. E. Seymour gave his lecture, entitled "Humble Beauties of the Flower World," on Monday, January 6. He drew attention to the fact that there is great natural beauty of a modest kind revealed in the despoiled weed of the fields and hedgerows, and flower photographers would do well to leave for a time their gorgeous roses and overgrow "Paderewski" chrysanthemums, and give a little attention to the humbler products of the wayside. Mr. Seymour's own exquisite studies of such amply prove the truth of his assertion. Most of his photographs are taken full-size, and he prefers a side lighting giving more relief. Mr. Seymour uses orthochromatic plates without a screen for his own work, and only uses a screen when requested to do so for professional work. He slightly over-exposed his plate, using pyro soda developer, and fixes the plate immediately the higher lights reach correct density, and, if necessary intensifying with mercuric iodide.

At the conclusion of his lecture, which was illustrated by some 180 studies, Mr. Seymour was accorded a hearty vote of thanks.

**SOUTHAMPTON CAMERA CLUB.**—The twelfth annual meeting of the above Society was held on Monday evening last. Mr. G. T. Vivian presided in the unavoidable absence of the President. The report and balance-sheet are most satisfactory, and proved that the club still maintains a strong and flourishing condition, which gives great credit to the management of this society. The officers were then elected for the ensuing year, and a vote of thanks to the retiring officials terminated the proceedings.

## Commercial & Legal Intelligence.

**A CINEMATOGRAPH BANKRUPTCY.**—A meeting of the creditors of Henry Chapman Whiteley, 17, Quay Street, Huddersfield, and Ernest Crossley, 127, Leeds Road North, Huddersfield, carrying on business as the Novelty Animated Picture Company, cinematograph and lantern entertainers, was held at the offices of the Huddersfield Law Society on January 3. The Official Receiver submitted a statement of affairs, showing liabilities £118 10s. 1d., and assets £43 17s. 6d., all of which was absorbed by preferential claims. The debtors commenced business on September 2, 1907, with capital amounting to £240, each partner obtaining £20 from his parents. Whiteley subsequently received £112 and Crossley £80, and both sums have been lost in trading. Amongst the creditors were the New Bioscope Trading Company, £28 10s. 3d.

**LEGAL NOTICES.**—Notice is given in the "London Gazette" that the partnership between John Thomas Roach, Harry Raymond Nathan, and Charles Warren Lovesey, practical cinematographists carrying on business at 12, Little Newport Street, Soho, as Ruffell's Imperial Bioscope Syndicate, has been dissolved.

In the cases of Carl Stackemann, photographer, of 4, Heathfield Terrace, Chiswick, who was adjudicated bankrupt early in 1907, and

lived Richard Maytum, photographer, of 27, Abbey Road, Torquay, who was adjudicated bankrupt in 1906, the trustees have just been released from their obligations.

**PARTNERSHIP DISSOLVED.**—Notice is given in the "London Gazette" of the dissolution of the partnership between Jas. Darman, Jm. Stocks, Jas. Dixon, and John Dixon, photographers, at Chester-Street, and Stanley (Durham). The business is to be carried on by Messrs. Jas. Dixon and John Dixon.

**THE CANVASSING FRAUD AT READING.**—Julian Michaelson, alias James Alexander, of Cardiff, was charged at Reading Police Court last week with obtaining money by false pretences.

Sarah Jordan, of 14, Mundesley Street, said prisoner told her he was travelling for Mr. Green, photographer, of Caversham, and asked witness if she would have one of her photographs enlarged free of charge as an advertisement for Mr. Green. She paid the prisoner 6d. for carriage. Witness did not have the photograph returned.

Emma Barlow, of 17, Sackville Street, and other witnesses, told a similar story.

Mr. Green, photographer, of Caversham, said he had never seen the prisoner before.

Detective-Inspector Anderson said that prisoner left his home at Cardiff four months ago, as he had stolen some watches there. He collected money on his brother's behalf but kept it, and at Oxford he had committed similar frauds to that with which he was charged that day, besides other frauds at Reading.

Prisoner was sent to gaol for a month with hard labour in each case, the sentences to be consecutive.

#### NEW COMPANIES.

**J. CHARLTON AND CO.**—This company has just been registered, with capital of £2,000 in £1 shares, to acquire the business carried on by J. Charlton, at 160, Edmund Street, Birmingham, as "J. Charlton and Co.," and to carry on the business of designers, illustrators, wood and photograph engravers, line etchers, copper-plate and steel engravers, etc. The subscribers are: J. Charlton, Mrs. S. A. Charlton, C. A. Mason, Mrs. N. L. Mason, W. Wincott, J. W. Pearce, and J. H. Charlton.

## News and Notes.

**PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.**—Mr. Louis Langflier has been elected on the committee.

**TRADE CLASSES FOR GIRLS.**—The London County Council propose to commence classes for instruction in the various branches of photography as an extension of the training in tailoring, corset-making, and other trades, which they have provided for girls.

**A GOLDEN WEDDING.**—Congratulations may be extended to Mr. and Mrs. John Davis, of Meadowside, Lancaster, on the celebration of their golden wedding this week. They were married at Lancaster Parish Church on January 4, 1858. For thirty years Mr. Davis has been known in the photographic world, and for fifteen years was a Fellow of the Royal Photographic Society, only retiring from business in favour of his son, Mr. T. S. Davis, two years ago. Mr. Davis's photographs have been accepted by Royalty. There are five children (two sons and three daughters), and fourteen grandchildren by the marriage. Mrs. Holmes, photographer, Lytham, one of the daughters, is a member of the Royal Photographic Society. Mr. and Mrs. Davis have received many beautiful presents. Although septuagenarians, they are in good health.

**LUTKE AND ARNDT.**—We are advised by Messrs. Lütke and Arndt, of Wandsbek, that from January 1 their firm will be continued as before, under the title of Arndt and Löwengard, whilst the Berlin branch of the business will be conducted under the management of Herr Richard Beifang, under the title Arndt and Löwengard, Filiale.

**COLOUR PHOTOGRAPHY AT THE P.P.A.**—This evening (Friday), January 10, a lecture will be given before the Professional Photographers' Association by Mr. Henry J. Comley, F.R.P.S., on "Colour Photography from a Professional Point of View." The lecture, which is open only to members of the

P.P.A., will be given at the house of the Royal Photographic Society, 66, Russell Square, at 8 o'clock. Members of the Professional Photographers' Association have already been notified of the fixture, but we may again draw the attention of London members to the lecture.

**EDINBURGH PHOTOGRAPHIC SOCIETY.**—The annual exhibition will be held from February 22 to March 7 in the Society's hall, 38, Castle Street, Edinburgh. There will be several open classes as well as some for members only, and in all the Society's medals will be placed at the disposal of the judges, Messrs. C. Martin Hardie, R.S.A., W. Crooke, and J. Craig Annan, to be awarded at their discretion. Entries close on February 8, and entry forms, which are now ready, may be obtained on application to the hon. sec., Mr. H. Stewart Wallace, W.S., 122, George Street, Edinburgh.

**VELOX COMPETITIONS.**—The prize winners in the current monthly competition organised by Messrs. John J. Griffin and Sons are as follows:—T. C. Howells, Widnes; Lawrence V. T. Grose, Bensham, Gateshead; Rev. F. Otley, Torquay; J. R. Grimshaw, Nelson; Walter Scott, London; John Chas. Bramley, Wibsey, Bradford; G. H. A. Currier, Alford, Lincs.; Ernest Pringle, Newcastle-on-Tyne; A. D. Collier, Whitby; D. G. Howell, Kensington; A. J. Shorter, Clapham; G. Nesfield, Wood Green, N.; John R. William, Burton-on-Trent; Miss Newham, Cheltenham.

**THE "RAJAH" CAMERA** offered monthly by Messrs. Rajar, Ltd., of Mobberley, Cheshire, for the best print on "Rajar" P.O.P., has been awarded to Geo. W. Hitchcock, St. John's Church Road, Bangalore, India, his print having been judged the best received during December. The paper on which the print was made was purchased from Messrs. Hitchcock and Son, Chemists, Bangalore.

**UNITED STEREOSCOPIC SOCIETY.**—The result of the Natural History Competition of this Society is to hand. The judge, Mr. Oliver G. Pike, F.R.P.S., made the following awards:—1st, Jasper Atkinson, Leeds; 2nd, A. T. Mole, Hampstead; 3rd, A. L. Fenton, Braintree. The following received hon. mention: Messrs. P. Dennis, B. Shalson, A. T. Mole, and Victor Selb.

**MYSTERIOUS DEATH OF A PHOTOGRAPHER.**—At Westminster last week an inquest was held on Herbert Holden, a photographer's printer, of Paddington, who was found dead in Hyde Park. It was stated by one of the park-keepers that he saw a man lying on his back with his arms outstretched on the grass late at night. It was extremely cold weather, and the man looked so ghastly that he called a policeman. The man was found to be dead. Holden's brother told the coroner that he had no doubt deceased had neglected himself. A short time ago witness sent him a box of eatables, and since the death of his brother he had found more than half of them at his house. The post-mortem showed that the deceased had had no food for some time. Death was due to poisoning from cyanide of potassium. The bottle contained a solution of that poison, which was used especially in the photographer's business. The coroner commented on the lack of motive which had induced deceased to take his life, and the jury returned a verdict of suicide, adding that there was no evidence to show the state of his mind.

**PHOTOGRAPHERS BY APPOINTMENT TO ROYALTY.**—The "London Gazette" gives lists, corrected and revised up to January 1, 1908, of the "tradesmen" who hold warrants of appointment to His Majesty and Queen Alexandra; also those permitted to style themselves, "By Appointment to the late Queen Victoria." In each case the firm is permitted to use the Royal Arms, but it is emphasised that in no instance may the Royal Standard be flown. The following are the photographers holding warrants:—To His Majesty from the Keeper of the Privy Purse: Chancellor and Son (Dublin), J. B. Ciolina (Frankfurt), W. and D. Downey (London), J. F. Langhans, photographer at Marienbad (Prague), Arthur Marx (Frankfurt), Mowl and Morrison (Liverpool), Carl Pietzner (Vienna), F. Ralph (Dersingham), Russell and Sons (London), T. H. Voigt (Hamburg), H. J. Whitlock (Birmingham). From the Lord Chamberlain:—Wm. E. Gray, fine art photographer (London), Hills and Saunders (Eton), Alex. A. Inglis (Edinburgh), Lafayette Ltd. (London), Wm. Oldham (to supply photographic chemicals), (Eton), Thomson and Son (London). Permitted to style themselves "By Appointment to the late Queen Victoria":—W. Abernethy (Belfast), T. and R. Annan and Sons (Glasgow), Brown, Barnes and Bell (Liverpool), W. H. Grove (London), Hughes and Mullins (Ryde, Isle of Wight), H. N. King (London), Lettsome and Sons (Llangollen), London Stereoscopic and Photographic

Co., Ltd. (London), Maull and Fox (London), A. and G. Taylor (London), R. Welch (Belfast), G. W. Wilson and Co. (Aberdeen). To the Queen, from the Lord Chamberlain:—W. and D. Downey (London), Kodak, Ltd. (London), Lafayette, Ltd. (London), W. S. Stuart (Richmond).

"PHOTO NOTES."—With the new year and the commencement of a new volume our miniature contemporary drops its sub-title, "The Bromide Monthly," and appears under the editorship of Mr. Welborne Piper, whose experimental work in several chemical processes related to bromide work, should ensure readers to "Photo Notes" some useful communications. The magazine is not, however, limited to bromide work, and the current issue contains notes and articles on "Bromoil," "Carbograph," "Daylight plus Flashlight," "Stand Development," "The Autochrome Process," "The Use of Negative Paper," "Black Tones and P.O.P." and "The Thiocarbamide Toning Bath," in all a goodly budget of practical information, which is surely not dear at 2d., for which sum "Photo-Notes" can be purchased from photographic dealers. It may be obtained, post free, 2s. 6d. per annum, from the publishers, The Rotary Photographic Company, Ltd., Moorfields, London, E.C.

CELLULOID IN JAPAN.—According to recent information (says the "Times") a factory is being equipped in Japan to produce five tons of celluloid and half a ton of artificial silk daily. Celluloid, as is well known, is made by treating nitro-cellulose with camphor, and Japan, including Formosa, furnishes about four-fifths of the world's supply of camphor, which is, moreover, a Japanese State monopoly for export purposes, and is constantly rising in price. It will be possible for the new company to employ its raw material either for the preparation of celluloid or for artificial silk in accordance with the state of the market.

"A VERITABLE FEAST OF COLOUR" is a time-honoured Daily-Telegraphese description of the stage-craft in costume and scenery which one is accustomed to find at the Alhambra Theatre, Leicester Square, but it is, nevertheless, an epithet justly applied to the ballets at this world-renowned house of entertainment. Probably many a user of Autochrome plates for portraiture or figure studies will pick up a hint from the almost endless variety of colour schemes in harmony and contrast to be seen on the Alhambra stage in a brief three-quarters of an hour. Apart from these educative features, the current programme includes a number of new performances, which make up an ideal evening's light entertainment for the jaded Londoner; they have the art at the Alhambra of putting on a show which is never dull nor yet a tax on tired brains.

DAYLIGHT DEVELOPMENT OF AUTOCHROMES.—M. Gravier, whose description of the dish for the daylight development of Autochromes appeared in the last issue of the "Colour Photography" Supplement, informs us that the dish is made in Paris by M. Mathieu, of 62, Rue des Marais, by whom it is sold at a total price of 10 fr. 75 c.

## Correspondence.

\*.\* We do not undertake responsibility for the opinions expressed by our correspondents.

\*.\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

### MAGIC MIRROR EFFECTS.

To the Editors.

Gentlemen,—In THE BRITISH JOURNAL of November 29 last appears a paragraph by Mr. Douglas Carnegie, in which it is suggested that suction by the pneumatic holder caused deformation in a glass plate. I beg to differ. I had the same trouble some thirty years ago when coating glass with collodion emulsion, and easily got over it without looking so far for the cause. It was due to nothing more nor less than a difference of temperature between the unprotected glass and the glass when protected by the pneumatic holder caused by the rapid evaporation of the collodion or similar substance while evaporating irregularly. In order to get over it I dipped the pneumatic holder occasionally in cold water before pressing it against the glass, and never again met with the trouble.—Yours very truly,  
4, Avenue Pinel, Asnières, Seine.

A. LEVY.

## Answers to Correspondents.

\*.\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

\*.\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\*.\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.

\*.\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C. undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

O. C. V. Aldis, 14, Victoria Pathway, Queen's Park, Chester. Photograph Marble Bas Relief, "The Head of Christ," by Donatello, Sculptor.  
W. H. Hewitt, Stubby Road, Dronfield, Derbyshire. Photograph of Dr. Rooth. Three Photographs, Interior Views of Dronfield Parish Church.  
A. Basil, 100, Tottenham Court Road, W. Three Photographs of the Rev. J. Akeley.

S.—None that we know of

BLACK TONES ON C.C.—Will you kindly give me the formulae for obtaining the rich black tones on aristo, platino, and other similar makes, and resembling the engraving black carbon? I am working the combined gold and plat. baths, but am not able to get the result I speak of, it either being a blue-black with toning to a chocolate in gold bath, or a greenish olive, with keeping print red in gold bath. I see in "Almanac" a formula where phosphoric acid is given in platinum bath. Would this give me the desired result?—R. D.

See the paper by Mr. Foster Brigham on another page. The phosphoric acid will not influence the tone.

REPRODUCTION.—Has a newspaper a legal right to reproduce photographs (if not copyright) without permission of the photographer? If so, must the name of the photographer appear underneath?—DOUBTFUL.

It has not, but under the Copyright Act no proprietor of copyright is entitled to any of the benefits of the Act unless the copyright has been registered. Legally speaking, we suppose newspaper has such right in the case of unregistered copyrights. We refer you to the article on "Copyright" in the "Almanac" for 1906.

ASTHENES.—We should judge the A outfit as most suitable. You cannot do better at a moderate price than write Messrs. Spiers and Pond, Water Lane, Ludgate Hill, E.C.

HONESTY.—Without being able to compliment you on your selection of a subject, we must say that the coloured card is obviously "colourable infringement" of your photograph, but as you have not registered the copyright you cannot proceed in respect of anything done up to now. After registration you can restrain both the actual makers of the card and those who sell it from making copies or exposing it for sale respectively. You had better be guided by a solicitor as to the best course to pursue.

OLD LENS.—Could you inform me, through your valuable paper, the value of lens marked "Lerebours, 4,453, et Secretan à Paris," sold by J. Atkinson, 33, Manchester Street, Liverpool? It covers  $\frac{1}{2}$  plate at full aperture. By so doing you would greatly oblige.—W. F.

It is without our province to value apparatus. The owner of it is always the best judge of the value it is to him. This lens must be a very old one, though it may be a very useful one. Its market value is probably not more than a few shillings.

GLAZING PRINTS.—Can you give me a good formula for preparing glass for glazing glossy bromide prints? I have been using for the past year pulp glazing boards, and they have got very scratchy. They cost me £10. I do not wish to buy new, as I should only have the same trouble again.—R. W. BROWN.

Make a solution up as follows:—Beeswax, 100 grains; benzole 1 pint. Pour a little of this on the glass, rub on with a piece of old flannel, and then polish off with another piece; or the glass

may be rubbed over with French chalk and the superfluous dusted off. If the latter method be adopted the prints should be alumed before they are squeezed on the plate, otherwise they may be liable to stick.

**TRADE MARKS.**—Would you kindly give me information how to register our names as photographic dealers, etc.?—T. CANN AND SON.

Write to the Comptroller of the Patent Office, Trade Marks Branch, Southampton Buildings, Chancery Lane, W.C., enclosing a penny stamp, and he will send you full instructions for the registration of your trade names. The matter is very simple.

**RESIDUES.**—(1) I have a large stock of very old plates (now practically unuseable), and I should be very glad if you will kindly inform me the best way to treat them for abstracting the silver. (2) Also, I have a large quantity of unmounted photographs (out of date) which I was thinking of burning down to ash, etc. Is it worth while?—F. B. REWOLF.

(1) The bromide of silver may be dissolved out of the films with a solution of hyposulphite of soda, the ordinary fixing bath, then the silver can be precipitated from that as a sulphide by sulphide of potassium (liver of sulphur). The sulphide of silver can be sent to a refiner. Unless you have a very large number of plates to deal with we doubt very much if the silver, when recovered, will repay you for the trouble and cost. (2) Not worth the trouble.

**P.O.P.**—(1) The lens you name is excellent, and will cover a plate well at a considerable angle—that is, a six-inch lens would cover half-plate. At the same time, we would dissuade you from using such short focus for cabinet portraits. (2) It would seem as though the defect is caused by occasional dewing on the lens. (3) We should say that, in the absence of any other arrangement, a quarter's notice is all that can be enforced.

**COMBINED BATH.**—Can you kindly give a cheap combined toning and fixing solution, suitable for toning postcards, cheaply?—POSTCARD. We can do no more than recommend you one or other of the baths on page 818 of the "Almanac."

**COPYRIGHT.**—I was photographed in Glasgow during the holidays, and am anxious to get a number of copies, as the photograph is a good one. The firm do not, however, use the sort of paper I prefer. I would like to have them done in carbon, and could get them copied and printed where I am employed. I do not know if this is permissible. I was told it was not, as the man who took the photograph could object. I have ordered and paid for half a dozen, and, of course, they are all merely for private distribution. I would be much favoured if you could tell me if I am laying myself open to any penalty in connection with copyright law by doing what I suggest. The photographer would require to send to a trade printer to get carbons done, and the price he named is quite out of reason.—COPYRIGHT.

Certainly, you are at perfect liberty to have the photograph copied, and neither you nor the printer who carries out the work is guilty of any infringement. As you paid for the photographs the copyright is yours.

**BENNETT CLARK.**—You had better apply to Newton and Co., Fleet Street. If they do not undertake the work themselves they will probably be able to tell you of someone prepared to make photomicrographs.

**ACETYLENE.**—1. As a user of acetylene gas, I should be greatly obliged if you can supply or advise me where to apply for particulars of what was reported as an explosion of an acetylene apparatus at a lantern show at Cardiff recently. 2. I get a good 9-ft. picture on the sheet with my lantern, and 6-in. focus lens. If I use a 10-in. lens, and get further away from screen so that my picture is 9 ft. diameter as before, lens being same diameter and light same in lantern, will last-named picture be as brilliant as the first, and if not, why not? With thanks in anticipation.—C. MASON.

1. We do not know any particulars beyond those already published. 2. If the same condenser is used with either lens there may be a difference due to the fact that the condenser works better with the one lens than with the other. Also with the 10-in. lens the light will have to be nearer the condenser, and,

provided the objective passes all the light that reaches it, the picture will be slightly more brilliant. If a longer focus condenser is used with the 10-inch lens, so that the distance from light to condenser is the same, then the pictures should be equally brilliant.

**J. J.**—We must refer you to our advertisement pages, where you will find the announcements of several such firms.

**H. W. H. P.**—We shall report and also reprint the lecture.

**DEVELOPING P.O.P.**—I should be glad to know if it is possible to develop P.O.P. after faintly printing, and then tone and get the usual tone at finish. Is Rodinal a good developer for above?—GEO. F. FRAMJEE.

Certainly it is; but after-toning, best in a combined bath, is necessary. Suitable developing formulæ are given in the "Almanac," page 819. Rodinal as purchased is not suitable. No doubt it could be used if acidified, but we have not experience.

**WAGES.**—You published some weeks ago a very useful summary of the Factories and Workshops Acts as applicable to photographic businesses, and I should be glad of your further valuable advice on the matter of payment or non-payment of assistants for extra holidays, such as summer holidays and absence in the event of sickness. That you may the better be able to give your opinion, it would perhaps assist you if I state my case more fully. I am running my business on high-class lines in highly rented and rated premises, and am assisted by two competent male assistants, in addition to considerable help from my wife. By reason of the quality of work produced and the fashionableness of clients, the margin of profit remaining after paying expenses and wages is barely a living one, and when making payment to assistants for a fortnight's holiday in the summer (in addition to all usual holidays) and absence in sickness, the duties usually performed by them devolve on myself, and necessitate prolonged and unreasonable working hours, often amounting to twelve, and sometimes more, hours a day, and I find that for the actual amount of hours worked my assistants are better paid than myself. What I wish to know—and it is an important consideration in a business such as mine—is, (1) Is it usual to give a fortnight's summer holiday, and necessary to give payment for such holiday? And (2) is it usual, and am I legally liable for payment to assistants when absence is due to sickness?

(1) It is. (2) It is usual, but we believe there is no legal liability in the case of sickness not occasioned by an employee's daily work.

**ACID AMIDOL.**—In the "B.J. Almanac" you refer to an acid amidol developer recommended by M. Balagny. I am told in his original work he writes of acid diamidophenol. Can you tell me if the same quantity of the latter, as the amount of amidol you quote, applies to the formulæ you give?—E. W.

We have not tried it, but amidol is practically the same substance as diamidophenol, and one can no doubt be replaced by the other in the formula.

**AUTOCHROME.**—Will you kindly give me your opinion as to cause of failure of enclosed Autochrome plate? I exposed it on a young lady, exposure two minutes,  $f/8$ , studio poor light. It looks as if it had not been exposed; but I was very particular to draw my slide, etc., as I had a failure something similar before. This is not my first attempt at Autochrome work, as I have three very good landscapes; but it is my first attempt at portraiture.—J. S. RICHMOND.

We should say the exposure was enough to give some sort of image, although it is none too much in poor light; but the appearance of the lightest parts only of the subject point to under-exposure. We could say more if you gave an actinometer value of the time. As it is, we advise you to test the light by Wynne or Watkins, and use  $f/8$  or P 1 as the speed of the plates.

**ARTIST.**—The "No. 3 B" lens of the maker named has an aperture of  $f/3$  and a focal length of  $11\frac{1}{2}$  in, and requires a distance of about 18 ft. between sitter and camera. Therefore it can be used in a studio 24 ft. long, though a little longer would be more convenient for working with it. No lens of that focal

length and aperture can be expected to cover perfectly to the edges. With regard to the second lens named, we have had no experience with it, and you do not say its focal length, so that we can say nothing as to what it should cover. However, by referring to its maker's catalogue we see that its aperture is but  $f/6$ , consequently it will require something like four times the exposure of the other, supposing both to be used with their full openings. With reference to your studio queries, we must refer you to the articles on the subject that appeared on pp. 635 and 659 of our volume for last year (issues August 25 and August 30).

**A BUSINESS QUERY.**—A lady came with a photograph and asked us to do her six copies for 11s. She paid 2s. on account, and said she would call the next week for them. She called and said they would do, but she had not the remainder of the money, but would call for them next week. We have not seen her since. Are we bound to deliver them to her before we can put her in the County Court for the balance? Or what would you do in such a case?—J. AND S.

We should say that you had better withhold the pictures till you get the money. If you deliver them to the customer you can then sue for payment in the County Court. The former would be least trouble.

**BLACK BACKGROUND.**—I should be much obliged if you can tell me if it is possible to make a perfectly black background out of a dark cloud one; and if so, what process of colouring would have to be gone through?—READER.

Yes, it can be done, and the easiest way would be to do it in distemper colour. In our issue of February 1 of last year will be found practical instructions for making distemper backgrounds, to which we must refer you, as space will not permit them to be repeated again in this column. In your case, it goes without saying, the whitening must be omitted, in order to obtain a quite black background, and lamp black, or drop black, used alone.

**A WAGES QUESTION.**—I should be much obliged if you will enlighten me on the following point. I am engaged in a business with some others, and a few weeks before Christmas we were informed by our employer that as the business was in a bad way he would have to deduct some money off our wages, at the same time telling us he would pay us our former salary, together with our deducted money, at Christmas. We have been on these short wages for some time now, and all applications for the deducted money are practically ignored. One of the assistants has now received notice. Will you inform me how he and the others can obtain their money?—PERPLEXED.

The only thing you can do is to sue for the arrears in the county court, if you cannot obtain them otherwise.

**H. AND D.**—I should be much obliged if you would inform me where I can obtain the necessary apparatus for "dry-plate" testing by the Hurter-Driffield system; also any literature bearing on the subject. I should be pleased to hear of anyone willing to give practical demonstrations of this system. Would an advertisement in the "Journal" to that effect be of any use? With regard to the literature, I have already the "Photo-Miniature" on the subject.—THOMAS ROUTE.

Apparatus from Sanger-Shepherd and Co., Grays Inn Passage, Holborn, W.C. There is no further literature in English except the book by Mees and Sheppard, "Investigations on the Theory of Photographic Processes" (Longmans, 6s. 6d.). A small announcement in our pages might certainly put you in touch with some one willing to give instruction.

**H. P. R.**—We will try them and report next week.

**E. R. Y.**—Houghtons Ltd., see under "New Materials" on another page; also Barton's, 114, Golden Hillock Road, Birmingham.

**JOHN DALTON.**—Fallowfield, 146, Charing Cross Road, London, W.C., and Billcliff's Camera Works, Manchester, S.W. For one exposure for all portraits you will require a camera with a number of lenses, but the most practical arrangement is a repeating back which can be adjusted to the various sizes.

**GREASE ON FINISHED PHOTOGRAPH.**—I have just had a 24 x 18 bromide enlargement made and worked up, first-class, in black and white for a specimen. While waiting to be put into its frame my boy upset, and broke, a bottle of sweet oil, some of which got on to the picture, and, worse luck, on the face. Can you tell me if there is any way of getting the grease off without injuring the working-up, which was done with water-colour, or is the picture entirely ruined?—R. J. W.

We do not think the picture is actually spoilt, as the oil can, probably, be removed by the following means:—Take some pure clean benzole, and pour a little on those parts where the grease is, let it rest for a minute or so and then blot off with clean white blotting-paper. By repeating this treatment several times the grease may be got out, and probably no stain will be left behind, and the water-colouring will not be disturbed. Even if it is, it will only be to such a slight extent that it can easily be repaired by the one who worked up the picture in the first instance.

**MASTER AND APPRENTICE.**—I have an apprentice bound to me for five years. He was a little over seventeen when he was bound by his father, since dead. I had a very small premium with him. Last week he told me he would not serve after another month, unless I paid him nearly three times what he is now receiving, as he would then be twenty-one. I told him that I should make him serve his full time, and he defied me. As he has now learnt the business, and is a very useful man to me, I want to make him serve his time. Can I take him before a magistrate for an order, or what steps must I take? I may mention that the indentures were made out by a solicitor, and properly stamped.—COUNTY PHOTOGRAPHER.

When the young fellow arrives at the age of twenty-one he can leave you if he chooses, as he is not bound to serve you longer. It would be of no use your attempting to keep him, unless you pay him what he demands. No apprentice can be compelled to serve after he attains his majority.

**COPYRIGHT QUERY.**—In the summer I arranged with a stationer in an adjoining town to take twenty views here and supply a print of each, to be reproduced by him (process blocks) and published by him as postcards. That he has done, and has sold many thousands of them. But I cannot get the money for my work; he keeps putting me off, though he is a well-to-do man, but has the credit of not paying anyone till he is obliged to. What I want to know is, if I were to make the pictures copyright now, as I have not been paid for them, can I prevent any further sale of them, or at least until he has paid me?—DOUBTFUL.

No, you cannot. In ordering you to take the pictures the man incurred a debt which is recoverable in the county-court. Although you have not been paid for your work the copyright is that of the stationer who gave you the order. Such a case as yours, "Boucas v. Cook," was decided a few years ago. Your only way of obtaining your money is by summoning the man in the county-court.

**J. A. WALTERS.**—Unless you can send us a specimen, we cannot say by what process it was made. From your description, however, we surmise it is a collodio-chloride print, toned first with gold, and afterwards with platinum.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Profitable Sides of Carbon Printing.—We draw attention to some applications of the carbon process, advantage of which might be taken by professional photographers. No 1 appears on page 40.

Some New Year's resolutions for a professional photographer include a higher standard of regular work, aims at correct exposure, novelties in styles, and more attention to book-keeping. (P. 39.)

Professional photographers are reminded that the right to use the Royal Arms is granted to a very few. (P. 37.)

We give on this page the names of those taking part in the exhibition of professional photography to be opened at the house of the "B.J." on February 6.

Some interesting experiences of Press photography were communicated by Mr. Reinhold Thiele at the Bolt Court School last week. (P. 42.)

Dr. Mees' lecture on screen-plate colour processes at the Society of Arts is reported on page 41.

A further departure in the Krayn screen-plate colour process, by which prints on paper are to be obtained, has been patented. (P. 44.)

The Progress Medal of the Royal Photographic Society has been awarded to Mr. John Sterry for his photo-chemical investigations. (P. 42.)

Mr. Martin Duncan has joined the staff of Messrs. B. J. Edwards and Co. as head of the cinematograph department. (P. 52.)

A patent has been taken out for the use of sodium thioacetate as the darkening bath in sulphide toning. (P. 44.)

What appears to be a re-invention of the ozobrome process has been patented in this country by Dr. Boerner. (Pp. 38 and 44.)

A non-spherical type of lens, for which aplanatism and great depth of field are claimed, has been patented by two French inventors. (P. 45.)

Dark-room clocks and cameras for balloon photography are among other patents of the week. (P. 43.)

Professor Michelson has published particulars of a new actinometer. (P. 38.)

A note on the cause of the dewing of lantern slides appears on page 38. Apparently the dewing is produced not simply by deposition of moisture on a cold surface.

## EX CATHEDRA.

### The "Royal" Progress Medal.

The award of the Progress Medal of the Royal Photographic Society to Mr. John Sterry should be received with satisfaction by everybody, for it provides the occasion of taking a review of the many scattered papers which its recipient has written during a period of experimental work which goes back now for a good many years. Had Mr. Sterry assumed more it is possible that the honour which the Society has to give would have been bestowed earlier upon him, but his modesty in speaking of his own work is at least as well known as the work itself, although Mr. Sterry is one of the few members of the Royal Photographic Society who is prepared to quote chapter and verse in contesting some point of the chemistry of, say, the latent image at which, very likely, he worked long enough ago for his results to have been forgotten. A portrait of Mr. Sterry appears on another page, and next week we shall supplement the brief notice which accompanies it by an article dealing more adequately with the series of experimental researches which have at length been accorded official recognition.

### The Exhibition of Professional Portraiture.

As announced last week, the Exhibition of Professional Portraiture arranged by the Professional Photographers' Association, will be held at the house of the "B.J." from Thursday, February 6, to Saturday, March 7. The Exhibition will include the work of the following members of the Association or of firms under the direction of members of the P.P.A.:—Edmund G. Ballard (Chepstow), G. C. Beresford (Brompton Road, S.W.), Gordon Chase (Tunbridge Wells), Henry J. Comley (Stroud), W. and E. Downey (Pimlico, S.W.), Ellis and Walery (Baker Street, W.), Elliott and Fry (Baker Street, W.), William Gill (Colchester), Hughes and Mullins (Ryde), Martin Jacolette (South Kensington, W.), Langfrier, Ltd. (Old Bond Street, W.), Percy Lankester (Tunbridge Wells), H. S. Mendelssohn (Pembroke Crescent, W.), John Moffat (Edinburgh), H. P. Robinson and Son (Redhill), Tom Reveley (Wantage), Miss Caswall Smith (Oxford Street, W.), H. C. Spink (Brighton), Sarony and Co. (Scarborough), Turner and Drinkwater (Hull), R. Fellows Willson (Sloane Street, S.W.), Drummond Young and Watson (Edinburgh). As in the case of previous exhibitions at the "B.J.," the collection is open for inspection daily from 10.30 to 4.30 (Saturdays, 10.30 to 12.30), on signing the visitors' book.

### Photographers in Reference to the list given last week to Royalty.

of photographers who hold Royal appointments, we may point out, for the benefit of many who address the query to us from time to time, that they, and

they alone among photographers, are entitled to use the Royal Arms in their businesses. This restriction applies equally to the use of the Royal Arms on show-cases, mounts, note-paper, letter headings, or anything else, and the penalty for disregarding it may be as much as twenty pounds. The letters we receive from persons who have had some photograph accepted by a Royal personage, or even by the King himself, show us that this condescension is frequently assumed to carry with it the right to use the Royal Arms. Such is, of course, an entirely unwarrantable assumption, for only those who hold the official Royal appointment have the right to signify the fact in connection with their business. We should add, too, that the use of a colourable imitation of the Royal Arms equally exposes the offender to a fine.

\* \* \*

### Ozobrome Re-Invented.

This week we publish what appears to be a new patent specification of the Ozobrome process. The special claim of the patentee, Dr. Rudolf Boerner, seems to be the discovery of the fact that the hardening of the image is accelerated by the use of catalytic agents, such as salts of cerium, iron, uranium, nickel, etc., but we are rather surprised that neither the patentee nor the Patent Office have made any reference to Mr. Manley's patent No. 17,007, 1905. The new patent forms interesting reading, but as regards the theory of the process we are inclined to think the inventor assumes a great deal. He does not give any proof that the metallic salts he adds do really act as catalysers, and he also attributes the hardening of the image solely to the formation of a chromium compound in the gelatine. There is, however, certainly some evidence to the effect that other substances are also formed in the image, and in the present state of our knowledge of this and other similar processes it is rash to attempt detailed explanations of the chemical mechanism of the actions that occur.

\* \* \*

### The Theory of Stereoscopy.

We reprinted lately an article by Dr. W. Scheffer, on a generally applicable stereoscopic correction formula, which article evidently considers the subject almost entirely from a mathematical standpoint. We feel, however, that it is very desirable to point out that stereoscopy is a subject that cannot be safely studied from this point of view alone. Numerous writers have so considered it, and owing to this fact many erroneous statements have been promulgated. Brewster himself made the same mistake, and many of his statements and conclusions are founded on purely geometrical figures and considerations, and not upon actual visual tests. Dr. Scheffer finishes his article with a law that he has "mathematically worked out," which gives a definite value to the apparent enlargement or reduction of dimensions and distances that may sometimes be detected in stereoscopic views when examined in the stereoscope. We have not tested his law to see if it is mathematically correct. We can take it for granted that it is so on paper, but we cannot for a moment admit that any such law holds good in practice. It is well known that some subjects, when taken and viewed under certain conditions, do appear different from the original as regards scale and distance, but if we test the matter practically we soon find that the alteration actually perceived bears no sort of relationship to the mathematically calculated state of affairs. Suppose, for example, we take a pair of photographs of a distant building from the extremities of a very long base line. If we mount the resulting prints in such a manner as to permit their being correctly viewed, then it can be mathematically shown that the effect should be that of viewing

a very small model of the original situated only a few inches from the eyes. But it can be practically proved in a few seconds, by actual trial, that no such effect is produced at all. The result will probably appear nearer than in nature, but its nearness and apparent small scale is limited by other most important factors that the mathematical exponents of stereoscopy unanimously ignore altogether, no doubt because such factors cannot be expressed in figures or formulæ.

### Dew on Lantern Slides.

Of late we have heard a good deal concerning the appearance of moisture on lantern-slides when they are subjected to the heat of the lantern. Every lanternist has remedies for this, and knows that if the slides are warmed before use the appearance is prevented, but every one does not, perhaps, know that this dewing of the slides is a phenomenon that is not very easily explained. If a piece of glass is taken from a cold atmosphere into a warm and moister one, such as that of a room filled with people, the glass is at once clouded with dew. Any one unfortunately compelled to wear spectacles is only too familiar with this fact. These, however, are not the conditions that prevail in the case of the lantern-slide, though many seem to think that they are. The air in the lantern is that of the room heated and partially dried. It therefore contains less moisture than the outside air to which the slides are exposed before being inserted in the lantern carrier. A feature of the dewing effect is its slowness. The moisture does not appear immediately. Some little time elapses before it shows at all, and it then slowly spreads. It will eventually disappear, but not for a very considerable time. In the case of the dew formed when cold glass is introduced into a warm moist atmosphere, the formation is almost instantaneous, and the disappearance is relatively rapid. The suggestion that the moisture is derived from fresh moist air drawn into the lantern is discounted by the fact that the freer the ventilation the less moisture is deposited, as pointed out by a recent correspondent. The most feasible theory seems to be that the moisture is carried into the lantern by the slide itself, in the gelatine and in the paper binding. The slow appearance of the dew, and the slowness with which it disappears, tend to confirm this view.

### A New Actinometer.

Professor W. A. Michelson, who is so well known for his researches in spectroscopy, gives in the "Physikalische Zeitschrift" a description of a new actinometer of his own design, which is apparently more sensitive than any existing instrument. The starting point of the new instrument was based on the action of the solar rays on a small sheet of mica, which is blackened on both sides and measures 60 x 12 mm. It is fastened at one end and is thus free to expand or contract as it is warmed by the sun. One end being fastened there is consequently distortion, the amount of which is read off. A still further improvement was made by substituting for the mica a sheet of platinum foil, of 0.025 mm. thickness, on which was deposited on one side only, by means of copper sulphate solution, a layer of metallic copper of 0.03 mm. thickness. To the end of this compound bimetallic plate is fastened an aluminium finger, at the end of which is a very small mirror. The whole is enclosed in a copper tube filled with water, which protects it from the action of the heat of the surrounding air. A small slit enables the instrument to be directed to the sky, and the variation of the position of the mirror can be read off by an eyepiece. Practically the new instrument may be considered as a pyrheliometer, or an instrument for measuring

the actinic variation of the light by means of the heat rays, which practically increase in a known ratio from the violet to the red end of the spectrum. The instrument is small and capable of very delicate and quick readings, thirty seconds being quite sufficient for one reading.

\* \* \*

#### the Use of Stills.

A writer in a contemporary advocates the use of home-distilled water, and while he admits that the law requires a licence for the use of retorts and stills, he suggests that no risk will be incurred, seeing that the strict enforcement of the law would seriously affect chemical education and research. We fear that this is by no means the view of the Inland Revenue authorities, and, as a matter of simple fact, many engaged in research work, and quite beyond suspicion of using stills for illicit purposes, have had serious trouble over this matter. No doubt many stills are in use for quite innocent purposes without licence or permission, but trouble on their account has only been avoided because the authorities do not happen to know anything about them. In any case the game is not worth the candle to photographers, seeing that distilled water can easily be obtained at 6d. per gallon or less. In a laboratory or factory where large quantities are used the case is different, but owing to the slowness of the process of distillation it is then generally necessary to keep the still constantly in use, and to work it in connection with a furnace or other heating appliance that is also in continual use. The photographer who only requires a few gallons occasionally will find little or no economy in distilling his own water, for the time that he will probably waste over waiting for a sufficient supply, added possibly to the cost of gas, etc., specially used, will more than counterbalance the cost of purchasing the small quantity that he requires.

#### A PROFESSIONAL PHOTOGRAPHER'S NEW YEAR'S RESOLUTIONS.

AFTER the depletion of one's pockets associated with the Christmas season, one's thoughts naturally turn with greater keenness to the question of their replenishment during the coming year.

Presumably photographers make good resolutions as the clock chimes midnight on December 31, and doubtless also they have already broken or forgotten their virtuous intentions. We venture in these notes, however, to suggest a few resolutions that may profitably have a longer lease of life than the rest of their kind.

One resolution that is being drummed into photographers in and out of season is to keep the showcases clean and bright, and frequently to change their contents. It is surprising how in the rush of business such essentials as display of one's most recent work are forgotten or pushed aside. Should any of our readers have been so negligent as to have left their Christmas shows unchanged they should immediately remedy the omission. We know at least one photographer who removed all his Christmas goods on Christmas Eve, opening with a fresh show after the holidays.

However cheap the class of work that may be done, a timely recommendation is that each sitter should be catered for as well as possible. It requires a very great amount of mental effort to treat each sitter as if a diploma depended upon the results, and too often the ordinary run of clients are treated in a mechanical fashion, reserving one's best self for sitters that are naturally pleasing, or from whom a big order is expected. Once get into the

way, however, of concentrating the whole mind upon each sitter, however plain or poor, and the work will improve with a bound. It is decidedly a strain to do this, but to do less is justice neither to the worker nor the customer.

One great thing that makes for good work is exposure; we would go further, and say no other part of the technical side of photography has so much bearing on the subsequent result. The professional photographer is popularly supposed to be infallible in this respect, but we believe that the majority of studio exposures are made with very little thought to light value or the diaphragm in use. The latitude of the modern dry plate is responsible for this state of affairs. Useful as this quality is, it is too often abused, for a greatly over-exposed negative often differs but slightly in appearance from a properly exposed one. This is the more noticeable in the case of a plate developed with pyro-ammonia, most formulæ for which are extremely kind to over-exposure. The difference in printing value, too, is not very evident, except to those who are used to perfect negatives, so naturally the man who over-exposes as a habit is unaware of his failing. To the critical eye, however, the difference between the brilliancy and withal softness of the correctly exposed negative, with its beautifully graded high-lights and rich shadows, and the flatter look of the other is at once apparent. The high-lights are the chief indications. They are blank and lacking gradation, not necessarily blank white, but without the subtle differences of tone that make the perfect print.

The general results may appear to a photographer to be good average work, whilst occasionally a really astonishing result is achieved in technique, and is put down to some kind combination of circumstances; this in all probability is that the latter is the one negative perfectly exposed. There is great latitude in exposure, but little latitude in the making of the perfect negative. Under-exposure is easily detected and shunned; over-exposure is more insidious, and therefore more dangerous.

The American fraternity appreciate the value of the larger size picture taken as an extra position. Very few Britishers speculate an extra plate and a little extra time, but it undoubtedly pays. It is advisable to use a lens for the ordered pictures that will also cover the larger size, so that the latter can be taken with little fuss or bother. A proof shown quite as a surprise is more telling than when the sitter is prepared to see a larger print.

The advice to study the old masters is still as necessary as ever, but the modern masters are quite or more helpful to photographers. The former advice can now be cheaply followed by purchasing reproductions of the different artists' works in certain sixpenny volumes, whilst the modern work is constantly reproduced in popular magazines, in Royal Academy annuals, and in our excellent contemporary, "The Studio."

Happy is the man who can strike upon a novel and original idea for his own exclusive high-priced line. If one cannot invent anything new one should certainly run a better-paying style than the average work, not only for the occasional wealthy sitter, but also to enhance one's reputation in the eyes of those who may be prospective clients. Paper mounts in folders, aërographed carbons, platinotypes with pencilled backgrounds, coloured Cosways are a few suggestions.

Office methods should receive more attention, and above all a set of simple books should be kept. This is all the more necessary as the income-tax gentlemen are extremely alert and pressing just now. Moreover, the contingency of ultimate sale, however remote, should constantly be remembered. The card filing system is one of the most useful aids to business and orderliness ever invented. Pirie Macdonald's or some other system should be installed immediately.

## PROFITABLE FORMS OF CARBON PRINTING. I.

WITHOUT wishing to suggest that carbon printing, pure and simple, is not a process capable of proving remunerative to those who practise it—in fact we hold a quite opposite opinion—we wish to draw attention to one or two variations of the ordinary procedure in which we think some emphasis may be laid on account of the use which can be made of them as means of profit-earning in the professional photographer's business. We are not exaggerating when we say that no printing process is so susceptible of modification, none is so readily applied (with very little actual departure from the accustomed method) to producing something distinct and novel in the way of a result, as is the carbon process. The changes which may be rung on colour of tissue and nature and texture of the final support of the print are almost endless, and are particularly appropriate to the methods of the professional photographer. It is not necessary to speak of many of these, since they call for no knowledge or experience additional to that which every carbon printer may be expected to have. But we may draw attention to one or two departures from the usual routine of the process, the practice of which, under suitable commercial conditions, may be reasonably expected to put money in the photographer's pocket.

In this first article we would draw attention to the use of the hand-made Japanese vellum papers, obtainable in this country of different substances and textures.

These papers are much used for impressions from engraved plates and photogravure plates, and the prints upon them are exceedingly fine. Some few of the higher-class photographers have for some time past employed them for mounting their best pictures upon. These are mostly platinotypes, sepia and black, and carbon, and the results are very artistic. The peculiar sheen—due to the long fibre of which the paper is made—on the Japanese paper is entirely unlike the surface of any other paper, and gives the picture upon it quite a unique appearance. In the case of engravings on these papers the impression, of course, is on the paper itself, and the effect is infinitely superior to that obtained when a print on another paper is mounted upon the vellum. Furthermore, when a print is mounted on the vellum, the latter becomes cockled, unless the mounting is done by the dry method. It goes without saying that, by the dry method of mounting, any pictures can be mounted on even the thinnest Japanese paper without the slightest cockling, but still the results are not the same as if the image itself was direct on the paper.

Yet carbon pictures in which the carbon image is direct upon the paper are easy to produce either by the single or double transfer method, as the Japanese paper is one of the hardest and toughest papers obtainable. Whichever method be used, the paper has to be coated with gelatine. If the picture is done by the single transfer process the paper has, of course, to be subjected to warm, or perhaps quite hot, water in the development of the image. These treatments entirely alter the peculiar sheeny surface which is the chief character of Japanese papers. There is, however, a method of obtaining the image direct on the naked paper without in any way interfering with its character, since the paper has neither to be wetted nor have any coating upon it. The method is, however, not very generally known, hence the present article. In a word, the picture is a double transfer one, developed on a temporary support and transferred to the Japanese paper—not in the usual manner, but in the following way: After printing the tissue is mounted on a flexible support and treated according to the usual practice,

except that it is not alumed. The ordinary commercial shellac flexible support is not suitable for our present purpose—at least, we have not been very successful with it, the reason for which will be alluded to later on. What should, and, according to our experience, must, be employed is the indiarubber temporary support that was used in the early days of the carbon process. That is simply ordinary good quality paper coated with a solution of indiarubber. This the user will have to prepare for himself, as it is not an article of commerce. A solution of indiarubber is made by solution in benzole so as to obtain a mixture about the consistence of very thick cream. The best kind of rubber to use is what is known as "masticated," which dissolves freely in benzole. Vulcanised rubber cannot be used, as it is insoluble in benzole. In making the solution it is best to make it thicker in the first instance than is required, and then to dilute it afterwards. If it is made too thin in the first instance it is more trouble to thicken it afterwards by the addition of more rubber than it is to thin down a thick solution. The most convenient way to obtain a suitable solution is to purchase, say, a pound tin of rubber solution as sold at the indiarubber shops, and thin it down to the desired consistence with benzole.

To coat the paper the solution is poured into a dish and the paper floated upon it for half a minute or so, avoiding air bubbles. Or the paper may be slowly drawn over it, when a smaller amount of the solution will suffice. When taken from the solution it is pinned up to dry, and as a considerable quantity of liquid will drain off, a second vessel should be put to catch the drainings, which, with more benzole added, can be used again, so as to economise the rubber. The paper is best coated a few days before it is required for use, so as to permit of the complete evaporation of the benzole. With regard to the paper itself, almost any hard, smooth paper will do, provided it will stand the hot water in the development of the picture. Any of the raw papers made for photographic purposes answer admirably.

This support is used in precisely the same way as the ordinary commercial flexible support, except that it has not to be waxed. It, with the exposed tissue, is immersed in cold water, the two squeezed together, and then, after resting the usual time, developed in the ordinary way, but without using an alum solution. It is finally hung up to dry. When dry, the face of the picture is coated with a solution of a soft gelatine, and again allowed to dry. The gelatine may be applied with a camel hair brush. The most suitable brands of gelatine for the purpose are such as Cox's soup gelatine, or Nelson's No. 2 soluble. Two ounces of either of these in a pint of water is a suitable strength to employ. If the ordinary flexible support be used the finer tints of the picture are liable to be disturbed when this gelatine solution is applied to the dry picture, but this does not happen when it is on the rubber support.

When the gelatine is dry the print is trimmed to size, and is ready for transferring to the Japanese paper. That is done as follows:—The gelatine coating is evenly moistened with a sponge lightly charged with water, but not made really wet. The Japanese paper, having been marked where the picture is to go, is laid on the bed of a rolling press, preferably with a roller heated, but not made very hot. The print, face downward, of course, is placed in position. It is then passed slowly two or three times through the press, when firm adhesion will be established. The whole should then be allowed to rest for an hour or two for the gelatine to get thoroughly dry, when the temporary support is removed. For this, a small piece of sponge is lightly charged with clean benzole, and the back of the support is gone over with it, just to moisten it. After resting two or three minutes the support can be lifted off,

and we then have our carbon picture direct on the Japanese paper without any intervening paper. Should any rubber be still on the picture it can be slowly rolled off with the ball of the finger, but that will rarely be the case. It was mentioned above that after the picture was developed it should not be alumed; the reason is that when alum is

used there would be sometimes a difficulty in stripping off the support, as alum seems to have a tanning effect on the rubber.

We must defer until the next article another application of the carbon process of which, we suggest, profitable use may be made.

## DR. MEES ON SCREEN-PLATE COLOUR PROCESSES AT THE SOCIETY OF ARTS.

A NUMEROUS company, in which were many well-known personages of the photographic world, assembled at the Society of Arts on Wednesday evening last, January 15, to hear a lecture by Dr. C. E. Kenneth Mees on "Processes of Screen-Plate Colour Photography." The lecturer illustrated his discourse with a number of experiments, diagrams, and specimens. His treatment of the subject differed from that of most of those who have lectured on or demonstrated the newer methods of colour photography, in that it said practically nothing on the practical manipulation of the plates, but dealt with the principles and methods of their manufacture.

Dr. Mees pointed out that the screen-plate was an additive method of colour photography, and the series of filters distributed between the glass of the plate and the film of emulsion required to have properties similar to those necessary in additive colour methods with three separate plates. The lecture demonstrated the mixture of coloured lights, which is the basis of the additive process. The mode of action of the screen-plate in recording colours was demonstrated with a screen, made by the lecturer, of the ruling of fifteen lines per inch. The lecturer next referred to the origination of the screen-plate idea by Ducos du Hauron in 1868. The next stage was reached by Professor Joly in 1895, at which time separate screens ruled on gelatine-coated glass were placed for a time upon the market. MacDonough, in America, had previously employed a similar process, coating plates with grains of coloured shellac and attaching these latter to the plate by fusion. MacDonough, however, gave up the grain method in preference for a linear screen, the manufacture of which was undertaken for some time in America. Two examples of the Joly process lent by Professor Joly were projected. Passing to the next stage in screen-plate colour photography, namely, the embodiment of screen and emulsion in one article, Dr. Mees credited Mr. Powrie with having been the first to carry out this process practically, and described the method of making the Warner-Powrie screen-plate. On projection in the lantern microscope, the divided blue line in the Warner-Powrie screen was seen, as was also the great mechanical perfection of the linear formation.

Alluding to the Lumière Autochrome plate, the lecturer gave the size of the starch grains as between 1-1,000 and 1-2,000 of an inch in diameter, and described the mechanical perfection of the plate as "astonishing."

In dealing with the Krayn screen-plate, made from sections of blocks built up with sets of red, green, and blue celluloid, it was pointed out that with a screen of very fine line the celluloid section must be very thin, probably so thin as to require mounting on glass. Moreover, if the line is to be very thin, the celluloid requires to be dyed very deeply to obtain colour filters of the necessary depth.

As regards the absorptive properties of the filters, the conditions of additive colour processes required that the taking filters should be such that the red had a sharp cut and transmitted no green or blue. The green required to overlap the red, and also the blue to some extent. The blue filter should transmit no red. In viewing filters, on the other hand, they needed

to have sharp absorptions without overlap. In screen-plate processes, where the negative obtained on exposure was converted into a positive, the taking filter became the viewing filter and a compromise had to be made between the two conditions. About the best compromise appeared to be the selection in which the regions of absorption touched, but did not appreciably overlap. Such was the case in the Autochrome plate. The effect of abrupt and overlapping absorptions in the projecting filters was shown by projecting the same transparency with the two kinds of filters: in the latter case degradation of the colours was produced. After detailing methods of testing the filters, Dr. Mees spoke of the first condition of a screen-plate, namely, its neutrality of colour. He found the Krayn plate the best in this respect, it being very slightly green. Warner-Powrie plates which he had seen were slightly violet, and the Autochrome plate faintly pink.

The thickness of the colour lines was an important point, because if the lines had any appreciable thickness in proportion to their width, parallax errors, arising from light falling on the plate at an angle, would be produced. This cause of limitation of the fineness of the lines was a far more serious one than the grain of the emulsion film. The fineness of grain of a rapid emulsion, such as could be used for panchromatic work, allowed of a screen as fine as 1,000 lines per inch.

The lecturer believed that the panchromatising of an emulsion of sufficiently fine grain would have to be done by bathing, and sensitiveness adjusted to the filters by the use of a yellow compensating light-filter. The adjustment of these conditions should be such that the screen correctly reproduced a scale of greys in neutral gradation. As regards the speed of screen plates, the lecturer estimated the sensitiveness of the Autochrome emulsion exposed through both the grain filters and correcting light-filter as about 1 Watkins. He thought that with our present knowledge of emulsions a speed of 6 Watkins could not be exceeded.

Dealing with methods of converting a negative into a positive image, it was pointed out that the sensitive film must be exposed and developed through to the back, and therefore required to be very thin. A direct method of reversing with a developer containing thiocarbamide might make it possible to use a thicker film of emulsion.

In printing a positive from a screen-plate negative, Dr. Mees explained the causes of faint or degraded colours due to overlapping of colour elements in the respective plates, and described Mr. Powrie's method of angling by which this obstacle to the making of perfect transparencies was overcome. In the case of colour negatives on Autochrome plates, the diffusion which took place in printing a positive was sufficient to give a fairly satisfactory result, but never one quite equal to a direct reversed positive.

Summing up the present position of screen-plate colour processes, the lecturer thought that their application at their present stage of development must necessarily be limited. Their opacity necessitated strong illumination

for projection, but their most immediate want was some improved method of bleach-out colour printing by which prints on paper could be obtained. As the full brilliancy of such bleach-out prints necessitated an angling movement to ensure full action over the bleach-out paper, the lecturer believed that plates with the colour filter elements in lines presented the greatest possibilities for the future.

The text of the paper will be shortly available in the Journal of the Society of Arts, when we hope to reprint it in full, together with a report of the discussion which followed it.

#### THE ROYAL PHOTOGRAPHIC SOCIETY PROGRESS MEDAL.

AWARD TO MR. J. STERRY.

It was announced at the meeting of the Royal Photographic Society on Tuesday last that the Council had conferred the award of the

John Sterry, Treasurer, Royal Photographic Society.  
Awarded "Progress Medal," January 14, 1908.

Society's "Progress Medal" upon Mr. John Sterry, "for his photo-chemical investigations, and especially for researches and writings on sensitometry, and on the action of substances on the latent image."

Mr. Sterry is one of the few workers who have repeated the experiments of Hurter and Driffeld, and others, in sensitometry, and he is one of the very few British investigators who have turned their attention to research and the latent image. At such short notice it is impossible adequately to review Mr. Sterry's photo-chemical work, but this will be done in an article by Dr. C. E. Kenneth-Mees, which we shall publish in our next issue.

**RÖNTGEN SOCIETY.**—The current issue of the "Journal of the Röntgen Society" contains a photogravure portrait of Dr. Thurstan Holland, better known, perhaps, to photographers as the president of the Liverpool Amateur Photographic Association. Dr. Holland was president of the Röntgen Society during 1904-5. The portrait portrays him in apparently almost an Instonian mood. The personality, possibly, of the unnamed photographer.

#### THE TRESS COMPANY'S PROFESSIONAL SHOWROOM

PASSING westward along Oxford Street, a few doors past Frascati Restaurant, a projecting sign is seen in white script on the right-hand side a step or two up Rathbone Place. It is an indication of the new premises of the Tress Company, known for its many special lines for professional photographers, and the new address—3, Rathbone Place, W.—will doubtless remain as common in the order book of many photographers as was that of 42, Oxford Street, where the firm's business has grown to its present dimensions within the short space of five years. In moving to Rathbone Place, the Tress Company has advantaged itself in several ways. It has installed enlarging facilities, which allow it to deal at once with urgent orders in the way of bromide and other enlargements. It has given itself space for a shop in which repairs to apparatus can be done for its customers; it is able to manufacture studio accessories and other of the professional requisites which it supplies; and, lastly, it provides on the street level a large showroom, in which the customer can see for himself the various forms of service which are at his disposal.

On the occasion of a visit paid within the last few days, we found Mr. Tress putting the finishing touches to arrangements which had been made during the upheaval of a removal from the Oxford Street premises. A few minutes' conversation with him brought to our notice a few of the inducements offered to professional photographers to visit Rathbone Place. In the first place, a portion of the showroom has been converted into an artificial light studio, and is fitted with incandescent gas, arc, and mercury-vapour installations. A camera in readiness for taking the customer's own lens is provided, as are also facilities for development by the customer of the test plates he may choose to expose. This offer to let the customer test a light before purchase should guarantee the Tress Company's *bona fides* as suppliers of all three forms of artificial light. Around the showroom may be seen examples of portraiture by mercury-vapour, etc., but the actual exposures must be more satisfactory to the prospective purchaser.

Among other features of the showroom are enlargements at the various and very moderate prices for the different styles, the print in each case being placed in the appropriate frame, also priced, thus: enlargement, 12 by 10, 3s. 6d.; frame, 2s. 9d. The firm also displays a great variety of mounts which it stocks, and can block to customer's order on the day of receipt of order for despatch the same evening. Studio chairs, settees, and accessories are also shown in a number of patterns and at very moderate prices. We were astonished to see what twenty or thirty shillings would purchase in the way of an oval table, carved settee, or terrace accessory. It is invidious to select any particular items from the many specialties of the Tress Company for professional photographers, but two may be singled out—namely (1) an order book (foolscap size), which provides spaces for the details of a sitter's order, and will accommodate 6,000 entries (price 2s. 6d.), and (2) a series of border prints for attachment to any mount, and sold as the "Rathbone." Each print has a central blank space, square or oval (where the photographic portrait is subsequently mounted), and is attached to almost any mount, giving, in the final result, a very effective Cosway style of picture. The above are but two of many novelties to be seen at Rathbone Place, but we have said enough to prove that photographers will not be disappointed in giving the Tress Company a call, or in applying for the new catalogue, almost ready.

#### A VETERAN ON PRESS PHOTOGRAPHY.

ON Thursday in last week the weekly lecture at the L.C.C. School of Photo-Engraving, Bolt Court, was on "Press Photography," and the lecturer Mr. Reinhold Thiele, one of the pioneers in photography for the Press, and still represented by his work in many newspapers and magazines. Mr. Thiele dislikes talking of himself, and though his discourse on the use of the camera in illustrated journalism was necessarily an account of incidents in his own career, he was silent as to his early training in Hanover and Hamburg, and his work as water-colorist and operator to the London Stereoscopic Company in Cheapside. But it was about twenty years ago, when Mr. Thiele established himself in business at his present studio in Chancery Lane, that he commenced to evidence the resource which has later made him the hero of many a photographic achievement.

Mr. Thiele's Press work commenced with a series of prominent sportsmen photographed on the scenes of their own records, among which was a number of portraits of cycling pace-makers apparently riding round the course, but nevertheless showing all the detail and definition not usually associated with rapid exposures—the ingenious Thiele had supported his mounted cyclist by a fine piano-wire secured to a fence in the background: the cycle could then be placed at the proper angle indicative of the rounding of the curve at high speed.

Mr. Thiele was one of the photographers to make early and effective use of flashlight, which, in the form of the Weiss lamp he employed very largely as an accessory to daylight in the photography of interiors or workshops and factories where a brief exposure had to be given in order to secure work-people in the act of carrying on their occupation.

Yet, as Mr. Thiele told his audience at Bolt Court last week, technical skill has sometimes to play second fiddle to mere human ingenuity, and he instanced a case in point in which he had to photograph a procession of the judges moving up a transept of Westminster Abbey. No flashlight there, yet a photograph had to be secured of a moving procession under conditions which the photographer knew meant an exposure of at least twelve seconds. The solution of the problem proved that when fast plates and rapid lenses have failed there is still the sangfroid of the photographer to be reckoned with. Having focussed upon a part of the route which the judges were bound to traverse, Mr. Thiele confessed to having inserted the dark-slide, drawn the shutter, and left the camera all ready for an exposure. Then he advanced to meet the procession as it entered the Abbey, led by half-a-dozen vergers, who, in turn, were headed by their senior. Meeting the procession while it was yet some way from the spot focussed upon, Mr. Thiele quickly explained the position to the leader. "I want you," he said, "when you reach that pillar simply to stop dead and count twenty slowly. Nobody will ask you why you stopped, and I can get the photograph." And he hastened to the camera in time to give an exposure to a number of his Majesty's judges, all of whom had pulled up in the field of the lens simply because the leader of the procession had obeyed orders.

Mr. Thiele's advice to the tyro in Press photography is: Conduct yourself in a seemly manner, but do not ask for permission if you see that you can get on without it. Usually if you ask you will be refused or restricted, but if you go about your work quietly, as a rule nobody will meddle with you. Good temper is equally a necessary part of the equipment of the Press photographer, and is particularly needed when, as is often the case, he has to obtain a portrait of some prominent person in the act of addressing a meeting or taking part in some public celebration. Mr. Thiele related the persuasion which he had had to exert in inducing a politician to rise for the purpose of a flashlight photograph. He was evidently speaking of the making of a photograph very different from many of those which appear now in the illustrated daily and weekly Press when no collaboration with the subject is sought by the photographer, and when, as a consequence, the portrait is often unrecognisable.

Asked by a member of the audience what aperture of lens was used on a certain occasion, Mr. Thiele confessed that he never knew at what opening the lens was employed when he took his picture. He was accustomed to stop down until he secured the desired definition of the subject, and he then judged the exposure by the brightness of the image on the focussing screen. For hand-camera work he had used a twin-lens camera very largely, although he had seen operators of Underwood and Underwood in South Africa make very effective use of a reflex camera. The latter was held upside down at arm's length above the head of the user as he sat on horseback. He had seen most satisfactory stereoscopic pictures produced in this way. As regards the choice of focal-length of lens in his own work, he tried whenever possible to use an angle of 45 deg., since it gave a more pleasing perspective than others, or, rather, permitted a point of view which gave good perspective.

Concluding with a brief reflection on the Press photography of the present day, Mr. Thiele assured his hearers that the comfortable times of a year or two ago were gone. Nowadays the Press-photography firm was kept informed every few minutes during day and night of any event to which it might be worth while to despatch

an operator. The Press photographer had to chase a lost airship across the three kingdoms and be finished with his work before the War Office officials appeared on the scene to restrict his further operations, not, perhaps, the happiest certificate of his smartness. With such resources as these behind the firms specially devoting themselves to the business, the individual photographer stood little chance. Mr. Thiele declared that the next inevitable step was the development of the plates and the making of bromide prints on the way back to London, but Mr. Newton, Principal of the Bolt Court School, gloomily reminded him that journalistic "hustle" would not have reached its limit until the half-tone printing block was made during the return journey of the Press photographer.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents have been received between January 1 and 4:—

DEVELOPMENT.—No. 31. Improved photographic developing machine. Magnus Niell, 88, High Holborn, London.

CAMERAS.—No. 32. Improvements in pocket cameras. Magnus Niell, 88, High Holborn, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

BALLOON OR KITE CAMERA.—No. 9,445, 1907. The invention consists of an apparatus by means of which the operator may be able to attach the camera to the balloon in such a manner that its angle of direction may be accurately set before the balloon is allowed to ascend, so as to control the angle at which the view is to be taken, or to compensate for the inclination given to the balloon by the force of the wind; also when using a focal-plane shutter, in such a camera, to employ a metal auxiliary shutter for protecting the fabric covering the plate from the direct action of light coming through the lens, except for a minute fraction of time, prior to and subsequent to the exposure of the plate.

It is also desirable that the camera attached to the balloon may be capable of taking several photographs without necessitating the hauling down of the balloon to the ground between each exposure, and also that some adjustment should be effected to enable the several exposures made during one ascent to comprise different directions and thus take several views instead of repetitions of the same view.

The figure is a cross sectional view of the camera.

1, is the hoop which is attached to the leading lines of a bal-

loon and forms the base of support for the camera, and also the point of support for a cross-tree carrying a bridle for taking the strain from the ground. 2 is a collar having a flange 3 thereon, situated within the hoop, and an interior rack 4 is carried on the flange 3 to which it is attached; the said flange 3 also supports a turn-table 5, which carries pending side frames 6, and on the lower ends of these side frames trunnions 7 are provided on which the camera proper 8 is carried and can be adjusted angularly.

9 is a pinion carried on a shaft 10 mounted in bearings connected to the turn-table and to one of the pending frames 6, and the lower end of this shaft carries a bevel wheel 11, which in its turn gears with an idle bevel wheel 12, and communicates therethrough with a further bevel wheel 13, carried on a spindle 14 mounted in bearings on the camera.

In this manner the camera is capable of being adjusted on its trunnions to any desired angle from the horizontal, at which angle it may be clamped by suitable means (not shown in the drawings) and by the rotation of the spindle 14 motion is communicated through the bevel gearing irrespective of the angle at which the camera has been set, in such a manner as to cause the turn-table to rotate within the hoop in accordance with the number of turns given to the spindle 14.

Clockwork mechanism is provided for storing sufficient power to enable the various movements required to be performed while the camera is in the air in order to take a series of photographs, and in the example shown in the drawing the mechanism has been arranged to take six photographs extended over an angle of 180 deg., so that each photograph will be taken about 30 deg. different in direction to the photograph preceding it.

John Edward Capper, Balloon Factory, Farnborough, and Griffith Brewer, 33, Chancery Lane, London, E.C.

**SCREEN-PLATE COLOUR PRINTS.**—No. 495, 1907. The invention relates to improvements in the method of producing three-colour screens for colour-photography as described in the British specification No. 1,938 of 1906 ("B.J.," July 6, 1906).

In the specification mentioned the production of lined screens for colour-photography is described. It has, however, been found that it is possible to produce from these line screens others which are composed of a number of colour points. These screens are obtained by uniting line screens (of a thickness equal to the thickness of their lines and produced in accordance with the previously mentioned methods) so as to form a homogeneous block, which is then cut into sections transversely to the lines of the layers of which it is composed.

The invention makes it possible to produce positives, which appear as coloured photographs, when seen from above, so that they make the impression of naturally coloured pictures on paper.

In order to produce such positive-screens the block from which the screens or veneers are cut is made not of transparent but of semi-transparent thin layers of the three primary colours. The abandonment of the transparency, however, must be carried out in such a manner that the colours possess the necessary brightness when seen from above. This, however, can only be attained if a white substance similar to china is the bearer of the pigment. If layers of nitro-cellulose are employed the transparent celluloid is made semi-transparent by adding a finely distributed white pigment such as zinc-white or the like, whereupon the celluloid becomes dulled in a suitable manner. The layers or bands in the three ground colours thus produced are piled up one upon another alternately so as to form a block which is cut into shavings transversely.

The shavings or screens thus produced are then covered with the panchromatic sensitive plate. The colour screen-plate negative is printed on the above-mentioned three-colour screen in such a manner that the panchromatic plate receives the light through the positive screen.

When developing the positive, the colour elements not required in the picture are covered by reduced silver, and after the fixing a picture is obtained which shows the natural colours of the object.

Instead of slicing the block in a planing machine into single shavings, long bands can be shaven from the former in a machine: for which purpose the block is made with rounded edges with a base parallel to the layers of which it is composed.

For the production of the block for the negative process as well

as for the positive process, the following method has been found to be the most suitable. Plates of about 1 mm. thickness are produced in the first instance by pouring or cementing the single celluloid layers one upon another in the three colours alternately. These plates, which are coated with the cement on both the surfaces, are assembled to the required thickness and are then united to a homogeneous block by means of hydraulic pressure.

This method represents a technical as well as an economic improvement of the methods proposed or used before as follows:

If the block is produced as proposed in the Specification 1,938 of 1906, many thousand single layers are necessary. If the block, for instance, is required to be 60 cm. broad and to possess 20 lines per millimeter, 12,000 layers are necessary. For piling up the layers one workman only can be employed at the time. But plates are produced in the first instance and are then united as to form a block, any number of workmen can be employed.

Further, if the single layers are piled up over each other until the required thickness is obtained it is not possible to obtain the lines absolutely straight. As soon as the block has obtained certain thickness it becomes more or less soft or a plastic mass which by its own weight as well as by the pressure caused by handling it necessarily undergoes deformations. These deformations cause slightly waved lines in the ultimate screens. This drawback is avoided if the plates produced in the first instance have so small a thickness that the single layers of which they are composed are necessarily parallel to the base on which they are piled up. Perfectly straight lines are thus obtained. This straightness of lines is maintained in the block, as the equal and even hydraulic pressure does not disturb it in any way. In case the block is not intended to be sliced into single layers but to be peeled off into long bands, discs are cut or stamped out of the plates manufactured as above, and are then assembled so as to form a block, with rounder edges. Robert Krayn, 24A, Marien Strasse, Berlin.

**"SULPHIDE" TONING WITH THIOSTANNATE.**—No. 12,364, 1907. The invention relates to the toning of photographic pictures by means of the thioannates of the alkali-metals and metals of the alkaline earths. Sodium sulphide, used for sepia tones, has the disadvantage of keeping badly, and even in the solid state it readily deliquesces and becomes oxidised. Sodium sulphide enters into combination with stannic sulphide forming well-defined crystalline compounds such as  $\text{Na}_2\text{SnS}_3 + 3\text{H}_2\text{O}$  (Ditte, *Comptes Rendus*, 95, 641) and  $\text{Na}_2\text{SnS}_4 + 12\text{H}_2\text{O}$  (Kühn, *Liebigs Annalen*, 84, 110), containing one or more molecules of  $\text{Na}_2\text{S}$  to each molecule of  $\text{SnS}_2$ , besides a varying number of molecules of water of crystallisation; and similar compounds of stannic sulphide with the sulphides of the other alkali-metals and metals of the alkaline earths are also well-known.

The inventors have now found that the thioannates of the alkali-metals or metals of the alkaline earths can be used instead of or together with sodium sulphide for obtaining sepia tones on silver prints. They possess the important advantages of being stable, non-deliquescent substances.

The following is an example of use:—

Prints, silver images of which have been converted into a silver-haloid by any suitable method, are washed, and toned in a solution of 1 part of sodium thioannate in 100 parts of water till the action is complete and then washed again; good permanent sepia tones are thus obtained.

The above preparations may be varied, or thioannates of the other alkali-metals or metals of the alkaline earths may be substituted for sodium thioannate.

This process may also be used for intensifying photographic negatives, as the image obtained is considerably more opaque to actinic light than the original silver image. Henry Solomon Wellcome, Snow Hill Buildings, London, E.C.; Arthur Gerald Bates, Dartford, Kent, and Frank Clement Starnes, Dartford, Kent.

**CARBON PRINTS FROM SILVER IMAGES.**—No. 19,889, 1907. The invention relates to a process of producing pictures, photographic printing plates, etc., hitherto made by the action of light on chromates.

Use is made of a reaction which metallic silver undergoes in contact with a solution of bichromates, ferricyanides and haloid or like (sulphocyanide) compounds, containing catalytic agents such as salts of cerium, iron, uranium, nickel, cobalt, vanadium,

titanium, manganese, mercury, copper, etc. Such solutions react with silver in the following manner:—

The potassium ferrocyanide which is formed is converted by the bichromate which is present into potassium ferricyanide, forming reduction-products of chromic acid, which are able to harden colloidal substances. Although the conversion of the silver into bromide of silver takes place almost instantaneously, it has been found essential to accelerate as much as possible the second phase of the reaction, i.e., the oxidation of the ferrocyanide into ferricyanide. This is done by adding catalysers.

According to the process, pigment pictures can be made from photographic prints, made on print-out or developed papers. For this purpose the non-fixed or preferably fixed and well-washed pictures are soaked in water, and a pigmented paper is pressed on to the damp copy, the paper being impregnated with the mixture of the previously mentioned substances. It has been found suitable to add glycerine to the liquid used for soaking. "Celloidin" (i.e., collodio-chloride paper) pictures, particularly where the paper is old, are advantageously soaked in alcohol, preferably with an addition of glycerine. If strong solutions are employed for impregnating the pigmented paper, it is preferable to remove the excess of the sensitising solution by weak pressure.

The pigmented paper can be developed whilst it is squeezed on to the silver print, or the pigmented paper can be separated from the print under water after sufficient contact, transferred in the usual manner on to paper, glass, wood, metal, etc., and developed thereon. The bleached print which remains behind can be re-developed and used again. If development is proceeded with whilst pigmented paper is in contact with the copy, it is preferable to free the finished picture from the silver compounds which have formed, as well as from silver which has possibly remained unchanged (say, by thiosulphate, or such together with ferricyanides), for the purpose of avoiding darkening. For gelatine prints a preliminary tanning with alum, formaldehyde, and the like is preferable before the pictures are employed for this pigment process.

For an original on printing-out paper a solution for sensitising the pigmented paper of about the following composition can be employed:—

Potass. ferricyanide .....	2 gr.
Potass. bichromate .....	3 gr.
Potass. bromide .....	1 gr.
Cerium sesquisulphate .....	0.17 gr.
Water .....	100 gr.

The quantity of the sesquisulphate of cerium can be increased two-fold; further, 0.1 gr. alum and 0.05 gr. citrate of potassium can be added to such a solution as the above. Also iron-alum or other iron salts can be employed together with cerium salts by adding about 0.085 sesquisulphate of cerium, 0.047 gr. ammonium-iron alum, and 0.05 gr. citric acid to the above solution. For employing two catalysers simultaneously it is preferable in many cases to use a weaker bath, such as is given for originals on developing paper, and to add to it in addition about 0.29 gr. sesquisulphate of cerium and 0.05 gr. citrate of potassium per 100 c.cms.

It is well to add to these sensitising solutions small quantities of substances such as alum, tungstate of sodium, which exercise a tanning action on gelatine, and to modify their tanning action by an addition of weak acids having no reducing action on chromic acid, acid salts or alkaline compounds of organic acids which are suited to convert the metals which have a tanning action into a complex compound. Likewise suitable quantities of easily volatile substances as alcohol, acetone, and the like may be added to the sensitising baths.

For developing-paper originals the following solution, amongst others, has been found suitable:—

Potass. ferricyanide .....	1.0 gr.	} in 100 gr. water.
Potass. bichromate .....	0.5 gr.	
Potass. bromide .....	0.5 gr.	
Sesquisulphate of cerium ...	0.085 gr.	
Ferric ammonium sulphate.....	0.095 gr.	
Citric acid .....	0.05 gr.	

Generally speaking, both for print-out papers as well as for developing-papers, a contact with the pigmented paper of three

to five minutes suffices with weak pressure, in order to obtain pigment copies capable of development.

The patentee claims to have recognised that the reduction of the bichromate when the above baths act on the silver print (i.e., the formation of substances, such as chromate of chromic oxide, which have a tanning action, and which produce the pigment picture) is accelerated by adding substances which act catalytically, such as the above-named salts of cerium, iron, uranium, nickel, etc., or mixtures of such compounds, to the sensitising bath which consists, as is known, of potassium ferricyanide, bromide of potassium and potassium bichromate. Dr. Rudolf Boerner, 125, Chaussee Strasse, Berlin.

**CINEMATOGRAPH MECHANISM.**—No. 15,459, 1907. The claim is for a cinematograph projecting lantern having a spur gear with a stationary axis, a handle for revolving this gear, a movable carriage, a pinion carried by the carriage and engaged by the gear, a spur gear fixed to the pinion, a second pinion carried by the carriage and engaged by the last-named spur gear, a shutter carried by the carriage, and mechanism through which the last-named pinion revolves the shutter. Siegmund Lubin, No. 21, South 8th Street, Philadelphia, Pa., United States of America.

**DARK ROOM CLOCKS.**—No. 10,538, 1907. The invention consists of mechanism of a clock which can be set to give a signal at the end of a predetermined time. The first claim specifies the means for determining the duration of the development in such a manner that the setting scale consists of arcs of circles of different lengths and provided with divisions, these arcs being designated to correspond with the markings on the scale of the seconds' index, their divisions being numbered in correspondence with the numbers given to the plates, so that by setting the index on one of the lines of the scale a double lever carrying a bell hammer is adjusted on a screw-threaded spindle, actuated by the clock-work in such a manner that this lever occupies exactly so much time in reaching its signalling position as is required for the complete development of the plate in question. George Lindsay Johnson, 55, Queen Anne Street, Cavendish Square, London, W.

**DIAPHRAGM SHUTTERS.**—No. 4,024, 1907. The invention consists in the mechanism of a shutter comprising time or bulb exposure parts and instantaneous exposure parts independent of one another, having an operating lever for setting the instantaneous exposure parts which, together with the spring actuating the latter, is unemployed during the manipulation of the time or bulb exposure parts, the entire operation of these parts being ensured by the disengaging lever or by bulb pressure. Wilhelm Kennigott, 64, Rue de Saintonge, Paris, France.

**CONCHOID LENSES.**—No. 4,527, 1907. The invention consists in an optical lens and the process of manufacturing it. This optical lens, which is applicable to all purposes, is characterised by its aplanatism, which is practically perfect, and its large field. A further advantage of the invention consists in the fact that this lens can in practice be employed alone without the employment of a second lens of different material as is usually done to render a lens achromatic. Finally the lens is characterised by the fact that it gives a sharp image of objects situated very close to the lens, say 16 inches away and up to infinity.

The considerations upon which the formation of a lens of this kind are based are as follows:—

Assuming a plane convex spherical lens, the intersection of which by the plane of the paper is  $bac$  (Fig. 1) and that  $da$  is the radius of the arc of a circle  $bac$ . Assuming also luminous point  $e$ , and  $ea$  as the ray emanating from the point  $e$  passing through the optical centre. The image of the point  $e$  should be formed at  $e^1$  on the prolongation of the ray  $ea$  encountering all the other luminous rays issuing from the point  $e$  and refracted by the lens. It is known, however, that this point of encounter is not a single point, the rays falling near the edge  $c$  of the lens intersecting the prolongation of the ray  $ea$  much nearer the lens than those falling near the centre. It is therefore necessary to cause the position of the point  $e^1$  to vary, or by causing it to vary very slightly to make the points such as  $f$  and  $g$  to coincide with the point  $e^1$ .

In accordance with the invention, this result is obtained by modifying the form of the discharge surface of the lens, in such a manner that the meridian of this surface, which from the summit  $a$  to the point  $h$  almost coincides with the circular arc  $a c$ , separates

from it progressively, whilst being external to it from  $h$  to  $i$ . In these conditions the rays emanating from the point  $e$  after their refraction in the lens meet at one and the same point  $e^1$ .

If in place of a plano-convex lens a convergent bi-convex lens be considered, it will be understood that the modification of the luminous rays on leaving the lens may be obtained in two ways; either as just stated, by modifying the admission surface in order to modify, by this very fact, the direction in the interior of the

Fig. 1.

lens of the refracted rays and consequently the direction of the rays leaving the lens. These two methods may, however, be combined; finally the meridian deformation curves may be internal to the meridian circle of the spherical lens in question, if it is desired to diminish the distances of the focal plane.

Starting from these considerations, it was first of all necessary to provide an apparatus permitting of tracing in a continuous manner in a plane, the deformation curves for replacing the meridian circle of a spherical lens. This apparatus as shown in Fig. 2 consists broadly of a bar  $j$  capable of sliding and turning around a fixed pivot  $j^1$ , one extremity  $j^{11}$  provided with a nut being traversed by a screw  $k$ . At the other extremity of the bar  $j$  there is fixed a pencil  $j^{111}$ . When the screw  $k$  is turned, the bar  $j$  slides over the pivot  $j^1$  and at the same time turns about it, and the pencil describes a right conchoid such as the curve I represented in Fig. 3.

By modifying the position of the pivot  $j^1$  relatively to the extremity  $j^{11}$  of the bar, curves are obtained like the curve II (Fig. 3) either internal or external to the circle taken as base.

Fig. 3.

Fig. 5.

Fig. 4.

Concentric curves may be obtained by displacing the pencil  $j^{111}$  and the position of the fixed pivot  $j^1$  simultaneously by the same amount; the curve IV concentric with the curve I is obtained in this manner. In the same way the pencil may be placed between the extremity  $j^{111}$  of the bar and the fixed pivot  $j^1$ ; the curve described is then analogous to that indicated at III, Fig. 3. The pencil may also be placed at the prolonged extremity  $j^{11}$  of the bar.

Instead of the extremity  $j^{11}$  of the bar describing a straight line, it may be compelled to describe a circle. In this case the screw is replaced by a disc. The circular conchoids obtained are analogous to the preceding curves. Fig. 4 shows the curve V described by starting from the circle VI as base. Concentric curves are obtained, Fig. 5, by moving the pencil up by a certain amount and

by decreasing the radius of the circle described by the extremity of the bar opposite to the pencil, by the same amount.

If without changing the radius of this circle the fixed pivot moved towards the pencil increasingly pointed curves are drawn by displacing the pivot in the opposite direction increasing elongated curves are obtained. It is therefore possible to draw deformation curves having the same summit and different curvatures, but in as close proximity as desired.

Fig. 6.

Fig. 7.

In order to form a lens, the summits of the curves such as those shown in Fig. 5 are combined.

For example, if it is desired to form a convergent lens, the summits  $l m n o \dots$  which form the interior curves internal on the side of the image are combined with the summits  $l^1 m^1 n^1 o^1 \dots$  which will form the exterior curves turned towards the object. It is also possible to combine the curves  $l m n o$  or to combine the curves  $l^1 m^1 n^1 o^1$ . The choice of these combinations will be determined by the important fact that in order to obtain

Fig. 8.

a good combination it is essential that the lens tested as a magnifying glass should give a magnification equal from the centre to the edge.

It is possible to employ the apparatus described above not only for tracing curves but also for cutting, from sheets of metal, templates which may be utilised for checking the lenses formed by the machine hereinafter described. To this end the pencil is replaced by a cutting point or knife, or by a milling cutter which is given an appropriate movement of rotation upon itself.

It is upon the general method which has been described that the

machine enabling optical lenses giving the results indicated to be formed mechanically, is based.

The machine is illustrated by way of example in the accompanying drawing Fig. 6 is a side elevation of the machine. Fig. 7 is a front elevation of the machine.

Broadly speaking the machine consists of a tool *p*, which will be described in detail, and which is mounted by the intermediary of a movable shaft 10 at the extremity of a rod or bar *q* which is capable of sliding on and turning around a fixed point, whilst the extremity of the bar opposite to the tool describes either a straight line or a curve of any kind.

The essential parts of the machine are a rod, one extremity of which describes a straight line, a circle, or any other curve, whilst turning and sliding on a fixed point. The other extremity carries a tool for shaping and polishing which turns upon its axis whilst describing in space the curve determined by the relative distances of the surface of the tool from the points of oscillation and attachment of the rod. The lens, to be worked, rotates around its axis in the opposite direction to that of the rotation of the tool.

In these conditions, the tool describes a curve, the nature of which depends upon the position of the fixed point and upon the nature of the displacement (straight line or curve) of the extremity of the rod opposite to the fixed point; the movement of the tool takes place whilst the piece of glass to be shaped rotates around an axis which is located and remains during the entire treatment of the lens in line with the symmetrical axis of the curve described by the tool.

The machine comprises a vertical stand *r*, fitted by any appropriate means to a bracket or to a foundation plate. On this stand *r* there is mounted a horizontal slideaway which is either cut in the stand itself or constituted by two bevelled bars *s* <sup>s1</sup>. A bar *t*, the sides of which are likewise bevelled, is capable of displacement in this slideaway. The bar *t* is provided with a stud *t*<sup>1</sup> on which the head *u*<sup>1</sup> of a connecting rod *u* may be mounted; this rod is variable in length by means of a sleeve *u*<sup>11</sup>, provided with a right and left-handed screw-thread. This rod terminates in a head *u*<sup>111</sup>, which is engaged upon a stud mounted on a disc *v*, which may be given a movement of continuous rotation. By means of the arrangement described, the continuous movement of rotation of the disc *v* is converted into reciprocating movement of the bar *t*. The amplitude of the reciprocating movement of the bar *t* depends upon the position occupied by the stud *v*<sup>1</sup> on the disc *v*. In order to facilitate the displacement of this stud, it is engaged in a slot *v*<sup>11</sup> arranged along a diameter of the disc *v*, and the stud may be fixed at any suitable part of this slot.

The bar *t* is formed with a slot *t*<sup>11</sup> (Figs. 7 and 8) in which a pivot *x* terminating in a tapered point *x*<sup>1</sup> is able to move (Fig. 8); this pivot may be fixed at any suitable part of the slot formed in the bar *t* by means of a nut *y* and counter nut *y*<sup>1</sup>; the enlarged part of the pivot *x* is screw-threaded for this purpose. The bar *q*, which, as above stated, carries the tool *p* at its upper part, is arranged parallel with the stud *r*. This bar is formed with a slot *q*<sup>11</sup> for the greater portion of its length. Through this slot there passes (Fig. 8) a socket 1 upon which there are fixed two cheeks 2 and 3 which are arranged on either side of the bar. A rod 4 in one of the extremities of which a cup is formed for the reception of the tapered point *x*<sup>1</sup> of the pivot *x*, is screwed into the socket 1.

The plate 14 being furnished with a lens to be worked, the respective positions of the tool and of the lens having been regulated in the manner described below, and the lower extremity of the bar *q* having been mounted upon the pivot *x* fixed at an appropriate point on the bar *t*, the lens is worked by starting the machine, that is to say, by giving a continuous movement of rotation to the disc *v*, likewise by transmitting a movement of continuous rotation to the shaft 10 of the tool *p*, but in the opposite direction, and finally by giving a movement of continuous rotation to the lens holder 14 also. In these conditions, the tool *p* will describe, in a plane parallel with the stand *r* and with the bar *q*, a curve, the form of which will depend upon the amplitude of the displacements of the lower extremity of the bar *q*, upon the position of the oscillation shaft or pivot 7 of the said bar *q* and upon the distance of the tool from the pivot 7. This curve will be a meridian curve, which will generate the surface of the lens to be

worked owing to the movement of rotation of the lens around a vertical axis situated exactly in line with the tool holder, located in a plane parallel with the bar *q* and coinciding with the symmetrical axis of the curve described by the tool.

In order to regulate the treatment of the lens, the following method is adopted.

The pivot of oscillation of the bar *q* having been fixed at the appropriate place, and the attachment of the bar to the plate 16 or to the bar *t*, as the case may be, having likewise been adjusted, the testing device 29 is slid along the bar *q* until the guide mark on the slide 29, which indicates the exact height of the point 33, comes opposite the previously selected division of the bar *q*; it will of course be understood that at this moment the lens 13 is depressed, that is to say the cup 14 has been lowered by means of the screw-threaded nut 26. The screw-threaded nut 22 is then acted upon in such a manner as to lower the tool *p* until it rests upon the point 33, and the exact position of the tool *p* is regulated in such a manner that the index 36 of the rod 32 is exactly opposite the zero of the scale marked upon the graduated sector 37. At this moment it is certain that the plane face of the tool is situated precisely at the desired distance from the centre of the fixed pivot 7. The index 39, which is movable over the graduation of the nut 22, is displaced until it comes opposite the zero of this graduation. When this has been done, the point 33 is separated from the tool by causing the testing or gauging device to rock around the hinge 31 and the lens 13 is raised by acting upon the screw-threaded nut 26 until the summit of the lens comes into contact with the tool. The tool is raised by an indefinite amount by turning the nut 22; then the bar *q* is displaced by hand, being caused to rock around the pivot 7 in such a manner as to bring the tool *p* to the right or left extremity of the meridian curve that it describes. When the tool has thus reached the left hand extremity, for example, of the meridian curve that it is describing, the bar *q* is stopped, and by acting upon the screw-threaded nut 22, the tool *p* is lowered until it comes into contact with the edge of the lens to be worked. The machine is then ready for action.

The disc *v*, the shaft 12 and the shaft 15 are started; the tool *p* continues to describe the same curve successively whilst it is turning on itself, as does also the lens 13, and this lens is worn down gradually. In proportion as the lens is worn down, the height of the tool *p* is adjusted by acting upon the nut 22 in such a manner as to lower this tool *p* constantly, and notification is afforded when the operation is terminated when by the successive actions upon the nut 22 the index 39 comes opposite the zero of the scale marked on the periphery of this nut. It will be understood that during the operation the grinding materials, such as emery and the like generally employed in grinding lenses, are caused to fall on to the face of the lens under treatment by any appropriate means.

The polishing and finishing of the lenses is effected on the same machine merely by changing the tools for tools of a different character. Georges Arsene Ossart, 4, Avenue Ossart, Seine et Oise, and Alphonse Emile Verge, of 8, Rue de l'Eglise, Vincennes, Seine, France.

AMERICAN PORTRAITURE.—Messrs. J. H. Dallmeyer, Ltd., inform us that they have had the collection of twenty-eight examples of portraiture by leading American photographers mounted on three panels, each measuring 44 x 33 in. They will be pleased to lend these to any societies which may wish to include them in their exhibitions, carriage being paid one way. The frames are fitted in a grooved box, which saves trouble in packing.

THE "ABELY" EDITED.—"Abel's Photographic Weekly" is brutally frank. It accuses its contemporaries in the States with filling 90 per cent. of their space with British matter, and in the next breath admits the same practice on its own part, with the extenuation that it is first with the lifting. Editorial motto of J. C. Abel:—"If that it is first with the lifting, 'twere better it were swiped quickly." "Just the same," proceeds the censor of his own people, "we all owe a mighty debt of gratitude to Messrs. Brown, Bagley, Hunter, et al., who have the welfare of our British contemporaries in charge." Bagley and Hunter? Who can these be?

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Stripping Films.

The cracked plate (writes Mr. L. Hodgson in "Photography") is placed, wet or dry, in a saturated solution of sodium carbonate (crystals) and left there for ten minutes. It is then taken out and left to dry. When dry, it is again placed in the same bath, and in a minute or two the film may be rolled off easily with the ball of the finger. It is then placed in clean water, where it swells to about double its previous size, but methylated spirit will reduce it again. But the film must not be put straight into the spirit from the soda, or the soda will crystallise out on the film. This process uses no acid, costs nothing, and has always given me complete satisfaction.

### Sulphide Toning of Bromide Prints.

In the second of his series of two articles in "The Amateur Photographer" on the above subject Mr. H. W. Bennett gives the following table of instructions for obtaining a range of tones from black to red.

Colour.	Bleaching Solution.	Darkening Solution.
Black .....	Ferricyanide, 1 part; mercury, 1 part	Sulphide.
Brown black .....	Ferricyanide, 2 parts; mercury, 1 part	Sulphide.
Very deep brown ..	Ferricyanide, 3 parts; mercury, 1 part	Sulphide.
Dark brown .....	Ferricyanide, 5 to 7 parts; mercury, 1 part	Sulphide.
Rich warm brown..	Ferricyanide.....	Sulphide.
Warm brown.....	Ferricyanide.....	Sulphide, 1 part; sulphantimoniate, 2 parts.
Very warm brown..	Ferricyanide.....	Sulphide, 1 part; sulphantimoniate, 4 parts.
Red brown .....	Ferricyanide.....	Sulphide, 1 part; sulphantimoniate, 7 parts.
Red chalk .....	Ferricyanide.....	Sulphantimoniate.

The ferricyanide, mercury, sulphide, and sulphantimoniate solutions alluded to above are as follows:—

A. Potassium ferricyanide .....	4 gr.
Potassium bromide .....	6 gr.
Water .....	1 oz.
B. Mercuric bromide .....	4 gr.
Water .....	1 oz.
C. Sodium sulphide .....	4 gr.
Water .....	1 oz.
D. Sodium sulphantimoniate .....	4 gr.
Water .....	1 oz.

## New Books.

"The American Annual of Photography, 1908." Edited by John A. Tennant. London: Dawbarn and Ward, Ltd.; New York: Tennant and Ward, and George Murphy. Price 2s. (in America 75 cents).

An annual of articles and contributions is this rejuvenated—we might almost say revived—issue of the "American Annual." Editor Tennant has called on the photographic writers of the States, and nobly have they responded. The result is an assemblage of articles, few among which can be disparaged as empty words. True, the theme of many a contributor is no new one, but none the less the total sum of the volume is a collection of hints and items which provide good reading and advice for the amateur worker and for many of his professional brethren. We may cite a few articles and their authors to show the variety of topics which is offered, and the much-desired "practical" character of the subject matter:—The possibilities of Kallitype, focal-plane cameras, the Kallitype process, mounting prints in albums, a universal developer, the pinhole for wide angles, the construction and use of a lens chart, a lens hood and its attachments, pyro and its preservation, notes on red-sensitive plates, paramidophenol as a tank developer, quick drying of

negatives, a simple portrait lamp, Ozobrome, Zeiss diaphragm markings, photography at night. For the rest, there are particulars of photographic schools of instruction, which might certainly be revised so far as those in Europe are concerned. There is no mention of the Bolt Court School, the Manchester Technical School, or the Regent Street Polytechnic, and it is a good many years since the late Dr. Vogel was at the Technische Hochschule at Charlottenburg. However, the volume does not pose as a compilation of standard information, although it has compiled a revised list of American photographic societies. The total number is only fifty-two out of one hundred asked to send particulars for publication. Society life in America must be in a more stagnant condition than here.

The annual contains a large number of illustrations, a good many of which are from the camera of Herr Dührkoop. Some others have been seen here at exhibitions, but the majority give us, presumably, an idea of the pictorial attainments of American workers outside Mr. Stieglitz's "Photo-Secession."

## New Apparatus, &c.

The "Compound" Diaphragm Shutter. Sold by A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, London, E.C.

In this very convenient type of diaphragm or between-lens shutter, Messrs. Staley have certainly reached a very high degree of efficiency. The shutter is very light, the working parts are enclosed, and the adjustments are most accessible. It provides time and bulb exposures, and a series of instantaneous exposures, which, as Messrs. Staley are prepared to prove, cover a range of from 1 second to 1-170.

which latter speed is to be increased to 1-250th in later deliveries of the instruments. Messrs. Staley are writing of the first small consignment of six shutters from which they have tested during the recent cold weather, with the following results:—

	1	1/2	1/5	1/10	1/25	1/50	1/75	1/100	1/250
No. 1.....	1	1/2	1/5	1/10	1/22	1/46	1/68	1/90	1/170
No. 2.....	1	1/2	1/4	1/10	1/22	1/50	1/75	1/98	1/175
No. 3.....	1	1/2	1/5	1/11	1/23	1/46	1/73	1/92	1/180
No. 4.....	1	1/2	1/5	1/10	1/26	1/48	1/75	1/93	1/180
No. 5.....	1	1/2	1/5	1/10	1/24	1/47	1/70	1/95	1/175
No. 6.....	1	1/2	1/5	1/11	1/27	1/46	1/72	1/88	1/165

The first line gives the marked speed; succeeding lines those actually found by test.

The shutter is actuated either by lever, bulb, or "Antinous" release.

The sizes in which the shutter is made and the prices thereof are as follows:—

	Shutter largest diameter aperture.	Inside tube diameter for lenses.	
No. 0 .....	1 1/8 in.	1 1/8 in.	55/-
" 1 .....	1 1/8 in.	1 1/8 in.	40/-
" 1a .....	1 1/8 in.	1 1/8 in.	42/-
" 2 .....	1 3/8 in.	1 3/8 in.	48/-
" 2a .....	1 3/8 in.	1 3/8 in.	54/-
" 3 .....	1 1/2 in.	2 1/8 in.	60/-
" 4 .....	2 in.	2 1/8 in.	65/-

The shutter is also obtainable in stereoscopic form, price 60s. and 75s.

## New Materials.

Wratten "Process" and "Process Panchromatic" Plates. Made by Wratten and Wainwright, Croydon. Sole Selling Agents: Hunters, Ltd., Poppins Court, Fleet Street, London, E.C.

Not only process workers and three-colour block makers will welcome two additions to the plates manufactured by Messrs. Wratten and Wainwright but photographers who have difficult work entrusted to them at times will be grateful for the assistance in certain special circumstances which the new introductions afford them. In these new plates, the makers have produced an emulsion which in certain important respects is certainly a distinct improvement on the materials hitherto available; that is to say, the qualities of general rapidity and freedom from interlaminar halation are highly developed, whilst the ability of the plates to give very great density by development alone is retained. In making negatives of line subjects it is thus easy to obtain the necessary opacity of the ground at the same time as the equally necessary transparency of the lines; in other words, one obtains the quality of negative which has been looked upon as the prerogative of the wet collodion method of working, in which the first developed image is strengthened with the acid silver or copper intensifier. But it is the photo-engraver, and particularly the three-colour process man, who will discover the advantages of the plate in the sharpness of the dot which can be obtained on them by quite uncomplicated methods. The plates are issued in both the ordinary and panchromatic brands, the latter a bathed edition of the former. The "Panchromatic process" is a very valuable material in making three-colour screen negatives by the direct process, as the emulsion gives clean dots and is rapid enough to allow of exposures as short as those with sensitised collodion emulsion.

We write as we do only after giving the plates a thorough practical trial, in the course of which they were seen fully to bear out all the claims made for them. They are certainly superior to any other unbatched process plates we have ever tried, and, of course, for making direct screen-negatives, the "Panchromatic Process" plate is superior to the ordinary Panchromatic plate, which we have formerly used with success. We have made both line and half-tone negatives, which have given us good prints on metal, without either reduction or intensification: there was ample density, and the spaces were quite transparent without any treatment whatever beyond development. On the other hand, in order to see the capacity of the plates for density, we may say that on merely intensifying a line negative with mercury and blackening with ammonia, the density has been so great that it was impossible to see a bright incandescent gaslight through the negative.

These plates certainly place a new power in the hands of the engraver, as, apart from three-colour, for certain black and white work they will prove invaluable, not only in saving time formerly consumed in photographing and re-photographing difficult originals (e.g., dark red silver prints and red carbon prints), but in making for a considerable improvement in quality in the reproduction of such originals.

The plates are sold at prices which are based on 1s. 6d. per dozen, in quarter-plate size for the "Process," and 2s. for the same size of "Process Panchromatic." As already stated the sole selling agents are Messrs. Hunters, Ltd., Poppins Court, Fleet Street, London, E.C.

A booklet dealing with the use of the new plates and also with other practical points in screen-negative making has been issued by Messrs. Wratten, and is obtainable both from them and from Messrs. Hunters, Ltd. The booklet discusses the properties of the ideal process panchromatic plate, and illustrates the difference in dot formation by a series of telling reproductions from screen negatives. It advises as to flash exposures on subjects of strong contrasts, and it also gives factors for the conversion of the daylight ratios of the plates, when used in three-colour work, into those which must be adopted when working by enclosed or open arcs, in short a good deal of practical information which, unless we are much mistaken, the photo-engraver will find it greatly to his profit to peruse. Formulae for the development of the plates and solutions advised for cutting and intensification, are also given in the booklet, which altogether deals very thoroughly with its specific subject.

## CATALOGUES AND TRADE NOTICES.

**LANTERN SLIDES.**—Messrs. Newton and Co., 3, Fleet Street, E.C., have issued a supplementary list of slides which runs to seventy-six pages, and includes particulars of many new sets of religious, literary, imperial and scientific interest, as well as of a large number of travel subjects. It is evident that Messrs. Newton still maintain their pre-eminence in the lantern-slide trade. A further pamphlet of the same firm describes the "Vitascope," a kind of long focus microscope designed for the examination of living objects under natural conditions.

**"FALLOWFIELD'S COURIER."** (Jonathan Fallowfield, 146, Charing Cross Road, London, W.) contains some comments on trade policy which makes its January issue worth reading. It also gives latest particulars of the Multisecto repeating back, whilst on another page we find Fallowfield pronouncing:—"That 'colour photography' is the future of the trade I have not the slightest doubt, and knowing the conservative nature of most traders, I have not been surprised to find dealers have not yet sold or bought supplies. This is a line which every energetic dealer should have cultivated, and there are many side lines of profit besides the discount on the plates."

**LETO PRINTING PAPERS.**—A new edition of the catalogue of the Leto Photo-Materials Co., 3, Rangoon Street, London, E.C., has been issued, and will be sent free to any photographer sending his name and address to the Leto Co. The list gives the brands, stock sizes, and prices of the P.O.P., C.C., bromide and gaslight papers manufactured by this well known firm.

A list of bargains in cameras, lenses, and other apparatus is obtainable from Messrs. Spiers and Pond, Queen Victoria Street, London, E.C.

**MESSRS. NEWMAN AND GUARDIA, LTD.,** have just issued their new catalogue and price list for 1908-9, the arrangement and general character of which are fully in accord with the high quality of the goods associated with the name of "N. and G." One of the special features is an art supplement, consisting of reproductions of work done with the various types of "N. and G." cameras, the originals being by well known photographers. An article on "The Importance of Shutter Speeds," by Mr. Arthur S. Newman, and also one on the "Autochrome Process," contains much useful information, and should prove of considerable interest to all classes of workers. In addition to their own well-known specialties Messrs. Newman and Guardia have now made arrangements to supply practically everything required for use in photography, and this latest list includes particulars of the most up-to-date apparatus and accessories on the market. Those desirous of possessing a copy of this comprehensive and artistic catalogue should make early application for same to the above firm, at 90 and 92, Shaftesbury Avenue, London, W., as only a limited number have been issued.

**"THE BRITISH JOURNAL ALMANAC."**—A testimony to the up-to-dateness of the "Epitome of Progress," the classified review of the year's doings which is a leading feature of the "B.J. Almanac," is wrung from a Continental writer, who, on other matters, has not been able to see eye to eye with Wellington Street. Reviewing a German year-book just issued, he deplores the late appearance of technical information published in the 1907 "B.J. Almanac," that is, a year in advance of the Continental abstract of progress. In further reference to the 1908 "Almanac," we may say on behalf of our publishers that their own supply of copies has long since been exhausted, and they can only refer those, who still send orders, to the wholesale and retail trade houses. We learn that one or two of the former have not a single copy on their hands, and therefore it behoves anyone who is still without his "Almanac" to lose no time in securing one from his most accessible source of supply.

**CELLULOID EXHIBITION.**—The German Celluloid Manufacturers' Association have decided to exhibit at the Exhibition Hall of the Berlin "Zoo" from February 12 to 24 next. The association desires to show the remarkable development of the celluloid industry and the multifarious uses to which the material is now successfully applied. They propose to exhibit not merely celluloid and celluloid goods, but the numerous articles of all descriptions into the manufacture of which celluloid enters. Information regarding the undertaking may be obtained from the association (Verband der deutschen Zelluloidindustriellen), 18 Neue Jakobstrasse, Berlin.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, JANUARY 17.

West London Photographic Society. "Time Development." W. F. Slater F.R.P.S.  
Sutton Photographic Club. *Photographic News*, 1907, Prize Slides.  
Hackney Photographic Society. Whist Drive.  
Nottingham Camera Club. "Bromide Toning." W. Murray.

SATURDAY, JANUARY 18.

Aberdeen Photo Art Club. "Rawlins Oil Process." G. L. Smith.

MONDAY, JANUARY 20.

Catford and Forest Hill Photographic Society. Monthly Competition. Criticism by A. H. Lisett.  
Harrow District Photographic and Scientific Society. "Scaloid." Demonstrated. Johnson & Sons.  
Kidderminster and District Photographic Society. "Tour in Ireland." G. F. Griffin.  
Stafford Photographic Society. "Warm Tones by Development on Gaslight Papers." A. L. Yapp.  
Scarborough and District Photographic Society. "Elementary Hints on Enlarging, introducing Home-made Apparatus." G. F. Bristow, Jun.  
Lancaster Photographic Society. "Weather and Weather Lore." G. W. Barrow, B.Sc.  
Southampton Camera Club. *Photographic News* Prize Slides.  
Bradford Photographic Society. Annual Meeting.

TUESDAY, JANUARY 21.

Royal Photographic Society. "Westminster Abbey." S. G. Kimber, F.R.P.S.  
Blairgowrie and District Photographic Association. "Trees and their Characteristics." W. D. M. Falconer.  
Epsom and District Literary and Scientific Society. "Gaslight and Bromide Paper."  
Rotherham Photographic Society. "Switzerland: Glimpses of its Mountains and Architecture." J. R. Wigtall, A.R.P.S.  
Worthing Camera Club. R.P.S. Affiliation Competition Slides.  
Sheffield Photographic Society. *Amateur Photographer* Prize Slides.  
Manchester Amateur Photographic Society. "The Evolution of an Amateur Photographer." Mr. Willis Brunt.  
Hanley Photographic Society. "Working up Negatives and Prints, including Use of Aerograph." B. J. Allen.  
Hackney Photographic Society. "Plea for the Negative and good Printing Technique." A. H. Blake, M.A.

WEDNESDAY, JANUARY 22.

Bristol Photographic Club. "The Autochrome Plate." M. B. Fowler.  
Central Technical College Photographic Society. Rotary Carbograph Paper.  
Borough Polytechnic Photographic Society. Lantern Slide Competition.  
Coventry Photographic Club. "The Theory and Practice of Time Development." W. F. Slater, F.R.P.S.  
Acton Photographic Society. Photographic Chemicals.  
South Suburban Photographic Society. "Carbon Printing." A. C. Braham.  
Woodford Photographic Society. "Systems of Enlarging and Reducing." W. L. F. Wastell, F.R.P.S.

THURSDAY, JANUARY 23.

Queen's Park Amateur Photographic Association. "Ozobrome and Carbon." David Horn.  
Chelsea and District Photographic Society. "Scenes in the Mediterranean." R. C. Gibbs.  
Rugby Photographic Society. "The Theory and Practice of Time Development." W. F. Slater.  
Middleham Photographic Association. "After Treatment of Negatives." Douglas H. Watson.  
L.C.C. School of Photo-Engraving and Lithography. "The Interpretation or Rendering of Subject and its Treatment." Will Rothenstein.  
Bath Photographic Society. Competition: Trimming and Mounting.  
Hull Photographic Society. Y.P.U. Portfolio.  
Richmond Camera Club. Rotary Carbograph Paper.  
London and Provincial Photographic Association. "The Lighting of the Optical Lantern." T. E. Freshwater.  
Blenheim Club. "A Recent Visit to South Africa." Rev. D. G. Cowan, M.A.  
Handsworth Photographic Society. "A Tour in Holland."  
Liverpool Amateur Photographic Association. "The Snow and Ice Scenery of Switzerland." C. Thurstan Holland, M.R.C.S., F.R.P.S.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, January 14, the President, Mr. J. C. S. Mummery, in the chair.

Mr. E. Howard Farmer read a paper entitled "The Modes of Action of Ruled and Analogous Screens and their Application to Photo-Engraving." Mr. Farmer reviewed the published papers for many years past in which the action of the half-tone screen had been dealt with. The conclusion was that both authorities and operators on the Continent and in America worked on the theory that the formation of the dot in the half-tone screen negative took place as though the aperture in the screen formed a pinhole image of the lens aperture. Operators based their work on that theory, and tables also based upon it were drawn up for their guidance. While it was true that the shape of the dot did agree in many cases with the shape of the diaphragm aperture, yet such was not the case in other circumstances, and he, the lecturer, could not agree that the pinhole theory was a sufficient explanation of the facts,

widely acknowledged as the pinhole theory was. The lecturer described a number of experiments in which the conditions prevailing in the use of the half-tone screen were magnified on such a scale that the phenomena could be easily observed, and he exhibited drawings and photographs showing that the shape of the dot was not necessarily that of the diaphragm of the lens. He then referred to other factors affecting the screen dot, such as diffraction, penumbra and irradiation, and he went on to point out that departing from the pinhole theory, it was possible to draw up formulae which greatly simplified the making of half-tone negatives and provided the operator with the means of making two or more adjustments simultaneously. Illustrations of the mechanism were shown and actual examples of the lens and fittings which have been placed on the market by Messrs. J. J. Griffin and Sons under the name of the "Ratiometric" lens were also shown. Some brief discussion followed the reading of the paper, Messrs. A. J. Newton, O. S. Dawson, and E. P. Butler taking part.

**SOUTHAMPTON CAMERA CLUB.**—Mr. S. G. Kimber, F.R.P.S., lectured at the Philharmonic (small) Hall, Southampton, on Monday evening, on "Westminster Abbey," before a large audience. Mr. Kimber, during the past year, has made a photographic survey of the famous Abbey, and is to be congratulated on the excellent collection of slides he has obtained, and which illustrated his lecture. He briefly referred to the architectural features of the exterior, but confined his attentions chiefly to the monuments in the interior, and gave a short biography of many of the celebrities whose memory is highly cherished. At the close Mr. F. G. Ryder proposed a vote of thanks to the lecturer.

**SOUTH LONDON PHOTOGRAPHIC SOCIETY.**—Lecturing on "Architectural Photography for Beginners," Mr. Edgar R. Bull, the well-known specialist in architectural photography, said that the best preventive of halation in interior work is to give a fuller exposure, and develop quickly with a developer containing a full quantity of accelerator, but only half the normal quantity of pyro, or other reducer. Backed plates are, of course, a *sine quâ non*.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—Ordinary meeting, January 9, 1908, Mr. T. E. Freshwater in the chair. The hon. sec. announced that arrangements for moving to the new meeting room had been completed, and that the first meeting in February would take the form of a smoking concert, to celebrate the occasion of moving. The smoking concert would be held in the new room at "Ye Olde Napier Tavern," 25, High Holborn, and it was hoped that a large party of members and friends would on that occasion make a special effort to be present. Mr. W. Thomas then lectured upon "Newspaper Illustrations by Means of a Hand Camera." Such work, he said, was daily becoming more important to those who desired to turn the use of the camera to a profit or to a means of making a livelihood. So far as the illustrated press went to-day, it could be roughly divided into two parts—the daily, and the weekly and monthly. With the first everything must be "right on top." One must first have the opportunity and avail oneself of it. It was of no use to send to the daily press pictures of something that had happened two or three days before, hence one must be wide awake and active; in fact, the essence of success with the daily press was speed. Yet one could use "intelligent anticipation" for one never knew when negatives of certain classes of subjects might be money-makers, as, for instance, some weeks before the wreck of the boat some time ago whose passengers were nearly all Britanny onion boys, he had secured a negative of one of these boys with his onions, proof of which, when the wreck occurred, was sent round to the press, and—well, now he had spent the money. With the weekly and monthly papers a more leisurely course could be taken, at the same time the work must be better, both technically and artistically. The first essential was perfect technique, next the ability to treat the most commonplace subject in an artistic manner. The press editors were becoming daily more and more critical, and when it was a case of choosing between a series of photographs, all perfect photographically, the one that was treated artistically was accepted. Slides were here shown, showing the advantages of using orthochromatic plates and light filters for the improvement of the work. Yet, said Mr. Thomas, do not over-correct your colour values. The lecturer also pointed out that it was better to treat subjects in series,

so as to fully illustrate a story or incident. If one was not a writer the editor could easily provide "the accompanying text." For his own work the lecturer used lens of 5½ in. and 8½ in. focus on a 4-plate, and also the "Adon" telephoto lens. The lenses should be of large aperture, to allow of quick work.

Mr. Teape, in moving a vote of thanks, said Mr. Thomas had been interesting and practical, and one had only to compare the illustrated press of to-day with, say, two years ago to see that the editors were becoming, as Mr. Thomas had said, more and more critical.

Mr. Rapson seconded, and Mr. Thomas suitably replied.

**EDINBURGH PHOTOGRAPHIC SOCIETY.**—At the meeting on January 8 a lecture was delivered by Mr. Robert F. Sherar, architect, on "Taste, Style, and Fashion in Art." Mr. Sherar said that, while inherent taste was the psychic force which produced art, what we understood by taste was constantly being affected by environment, experience, and education. The adoption of fashions in art showed a want of taste. He said it was almost impossible to judge of art work of a novel character, as the only sure test was that of time and continued admiration. The lecture was profusely illustrated by limelight views of architectural styles, showing how these had been affected by social, physical, and geographical considerations.

**SOUTH SUBURBAN PHOTOGRAPHIC SOCIETY.**—"Why Should London Wait?"—Lecturing last week, at Plough Hall, Lewisham, Mr. A. H. Blake, the well-known pictorialist, expressed surprise that London was so much neglected by photographers in search of subjects. Though the picturesque relics of the past were fast disappearing, he said, there were still many objects of interest left, and not a few subjects for pictorial treatment. Amongst the slides that illustrated his lecture was quite a number of both; but perhaps the most successful were the sunlight effects obtained in the leafy squares of London and the reflections secured upon London's river. The lecture itself was like a little history, which had fallen into its anecdotal, and was garnished with apt quotations, which gave actuality to the street names with a story.

**WOOLWICH PHOTOGRAPHIC SOCIETY.**—Mr. E. Seymour gave his lantern lecture on "Flower and Fruit Studies" last week. He stated that he worked with ordinary plates and simple apparatus, and without a yellow screen. Most of his studies were the common flowers and grasses of the fields, which were supported upon a small table covered with brown paper. He wired the leaves and stems, or pinned on additional ones here and there to alter the position and obtain the required effect. A long exposure was given in a small room with a side light, the window being covered with cambric and no reflector or screen used, but by means of oil to touch up the leaves a reflection was readily obtained. The slides shown were excellent, and, with the lecturer's humorous remarks, contributed to a most pleasant evening.

## Commercial & Legal Intelligence.

**ANDRE AND SLEIGH, LTD.** (Photo-Engravers, Bushey).—Issue on January 1 of £7,700 5 per cent. debentures, part of series created December 19, 1907, to secure £8,000, charged on the company's undertaking and property, present and future, including uncalled capital. No trustees. No previous issue of same series. (Out of the above-mentioned £7,700 the whole previous issue of £7,000 has been satisfied.)

**LEGAL NOTICES.**—Notice is given in the "London Gazette" of the release of the trustees in the bankrupt estates of John Grange, photographer, of 25, High Street, Loughborough, Leicestershire, who was adjudicated bankrupt early in 1907, and of John Easden, photographer, of 21, Union Street, East Stonehouse, and 6, Tavistock Road, Crownhill, both in the county of Devon.

**CANVASSING FRAUDS IN ESSEX.**—At the East Suffolk Quarter Sessions last week, George Havard, canvasser, and John Havard, photographer, were charged with obtaining 5s. by false pretences from Frederick Alexander, at Capel St. Mary.

Matilda Scarf, wife of a coachman at East Bergholt, spoke to a visit from the defendants, who wanted to take a photograph of her house with witness and Miss Howlett standing on the step of the door. Afterwards they photographed the two of them with the

cook of the house. Later on the elder prisoner called with a proof, and asked for the money. The postcards bearing the photograph were 2s. a dozen, and orders for three dozen were given by witness and two servants, the printed receipt bearing the address of 46, Station Road, Sudbury. The postcards were promised in a fortnight's time, but they never arrived. In consequence Miss Howlett sent a postcard, but got no reply, nor had they received their money back.

Emily Cooper, of Higham, who received a visit from the prisoners in September, said they took a photograph of her little daughter. The elder called next day with a proof, and she ordered half-a-dozen for a shilling. She parted with the money on the understanding that the photographs would be delivered in a fortnight. She had neither received her photographs nor her money.

Minnie Eleanor Reeve, wife of the postmaster of Capel, spoke to the prisoners photographing her and her children outside the house, but added she never received the portrait, though a proof was produced.

Charles Carter, blacksmith, of 46, Station Road, Sudbury, said the prisoners came to him in June, and left on October 15. They had a sitting-room, a bedroom, a cellar for developing, and the scullery for washing. The prisoners received a great number of letters, and they discussed these with him, and witness read many of the postcards, which asked for photographs, and also threatened proceedings.

John Havard, who was then called, said his name was Andrew Gale; he traded under the name of John Havard and Co. After setting up in business at Sudbury he wrote to his brother, and induced him to canvas for £1 a week. After taking photographs, he generally went round the next day with the proofs. He got orders upon them, and gave receipts. His mode of business was to have the cash in advance, and that was what most travelling photographers did. The prisoner added that he used the best kind of camera and other expensive photographic apparatus. He had every intention of executing his orders, and got so busy that he ultimately took into his employ the daughter of the witness Carter. He paid her 5s. a week, and paid the father 1s. a week for allowing her to work for him. The season was a bad one for photography. The girl was engaged in finishing postcards and views, and he sent out large bundles of finished prints. Unfortunately his work fell into arrears, and it was the absence of bright weather that prevented him from completing his orders. He was greatly surprised when the police arrested him, because he was then printing and sending a lot of stuff off to the customers.

Prisoner would not deny that he took money from 140 people in West Suffolk, and only sent photographs to twenty of them. He could not tell without his records whether he took money from 134 people in Essex, and sent photographs to only sixteen.

George Havard, who was also called, said his name was George Gale. He always acted under his brother's orders, and after he was taught he did some of the printing. When it was fine, over 100 postcards were printed a day. He had taken out hundreds of photographs, sometimes as many as twenty and thirty a day. He had nothing to do with the business more than he employed by his brother.

The jury found the prisoners guilty.

Supt. Taylor said the elder prisoner had received six months' hard labour for embezzlement in the North of England in 1905. He held a warrant against him from the Gateshead police, as well as one from the Essex police in connection with the present case.

The Magistrates sentenced the elder prisoner to ten months' hard labour, and the younger one was bound over in the sum of £10 to come up for judgment if called upon.

### NEW COMPANIES.

**CHARLES MURRAY, LTD.**—£500 in £1 shares. To take over the business of a chemist, druggist, and optical and photographic manufacturers' agent and dealer carried on by C. Murray at 1, City Road, Winchester. 1, City Road, Winchester.

**PHOTOGRAPHS OF HOLLAND.**—Messrs. A. E. Staley and Co. remind us that the collection of photographs made by Mr. Stanley Fincham of subjects in Holland, and with the Enryplan and other lenses, is still open for inspection at 19, Thavies Inn, Holborn Circus, E.C.

## News and Notes.

**THE COTSWOLD PUBLISHING COMPANY**, Collotype printers and plate-makers, inform us that their address after the 30th inst. will be Britannia Mills, Wotton-under-Edge, Glos., where all communications should be addressed.

**WINNER OF EAU DES CARMES COMPETITION.**—A large number of very striking photographs have been submitted in this competition, and the proprietors of Eau des Carmes have finally decided to award the prize of £10 to Mrs. Whitten, 21, Coventry Road, Ilford. Cheque for that amount has been posted her.

**SHEFFIELD PHOTOGRAPHIC SOCIETY.**—The annual exhibition will be held from March 31 to April 4. There will be six open classes, including one for colour photography, in all of which bronze plaques and certificates will be placed at the disposal of the judges for award. The society, working in conjunction with the executive of the Nottingham exhibition, have made arrangements for the free collection and carriage of exhibits from the Birmingham and Ilkeston exhibitions to Nottingham, and thence to Sheffield. The hon. sec. is Mr. James W. Wright, 62, Vale Road, Sheffield.

**CRIPPLEGATE PHOTOGRAPHIC SOCIETY.**—The annual exhibition will be held in the large hall of the Cripplegate Institute, Golden Lane, from March 16 to 19 inclusive, latest date for receiving entries March 2. There will be several open classes, in which bronze medals will be placed at the judges' disposal for award, with the addition of a silver plaque for the best picture in the open champion class. The society have made arrangements whereby pictures shown at the exhibition of the South London Photographic Society may be collected free of cost to exhibitors. Entry forms, which are now ready, and full particulars, may be obtained from the hon. sec., Mr. W. J. Middleton, 1, Foresters' Hall Place, Clerkenwell, London, E.C.

**MESSRS. GRIFFIN** announce that they have engaged the services of Mr. H. Holt as technical expert in process matters. Mr. Holt recently held the position of manager to the process engraving business of Messrs. Taylor, Garnett and Evans.

**FIFTH AVENUE PROFESSIONALS.**—"I see," writes J. C. Abel in his "Photographic Weekly," "Mr. E. B. Core's name down on the list of fortunates who have secured tables at the Knickerbocker Hotel for New Year's eve. He's in mighty good company, what with the Goulds and Astors and others at neighbouring tables. But then 'Pop' Core is a mighty good company in himself. I think I can guess who some of his guests will be.

"With Marceau and Core running automobiles, Hollinger with a beautiful little estate on the Palisades, Bradley, Histed and others with Newport studios, Puffer with a most enviable Palm Beach clientèle, MacDonald and Mrs. Käsebieber with frequent trips to Europe, do you wonder that photographers everywhere cast a longing eye on 5th Avenue as the Ultima Thule of the photographic profession?"

**THEFT OF A CAMERA, ETC.**—The details of a man's chequered career were given before the Clerkenwell Police Court last week, in the case of Morris Meyer Cohen, 49, dealer, who pleaded guilty to stealing a camera from the shop of the London Stereoscopic Co., Ltd., Regent Street, and a pair of binocular glasses from Sinclair and Co., Ltd., Haymarket. Detective-Sergeant Burton proved that in 1897 the prisoner was ordered six months' imprisonment, and in 1906 one month for shop robberies. Mr. Purcell, who represented the prisoner, said he was the son of a former managing clerk to a City firm, and on that gentleman's death unfortunately prisoner was left in embarrassed circumstances. This led to his first conviction. After the sentence he went to South Africa, and prospered in business until the outbreak of the war. Finding his business then ruined, he volunteered for service, and remained in the field until invalided with enteric fever. He was sent to hospital, and on recovering was appointed the captain of the Town Guard at Cape Town. There he lived creditably until 1904, when he returned to this country. Since

then he had lived by collecting rents and debts and acting as a private inquiry agent. Want, however, had brought him back into crime. His friends would after his sentence send him back to South Africa, so that he could start afresh. He was sentenced to nine months' imprisonment.

**THEFT BY A PHOTOGRAPHER.**—Charles F. Lamore, a photographer, of Portsdown Road, Maida Vale, was charged at Westminster with stealing a silver toilet box from 49, Eaton Terrace. The accused called at the last-named address, under the pretence of requiring apartments. Some rooms were shown him, from one of which, immediately after his departure, a silver box was missed. Prisoner was given into custody by the landlady of the house and the missing box found in his possession. The case was remanded.

**ART IN COLOUR PHOTOGRAPHY.**—Mr. Stieglitz, in his "Camera Work," announces that the promised reproductions of Autochromes by Mr. Steichen are not yet completed by the Munich firm of Bruckmann, which is preparing them. Meanwhile, the "Studio" for the current month, published in London on Tuesday last, contains a reproduction of an Autochrome by Mr. A. L. Coburn.

**MR. F. MARTIN DUNCAN**, who is so well known for his photographic and natural history cinematograph work, has now joined Messrs. B. J. Edwards and Co. as the head of the cinematograph film stock department.

**"COMMERCIAL PHOTOGRAPHY."**—Messrs. J. C. Mengel and G. W. Wagner inform us that, having lately acquired the Kingsbury Works at St. Albans, Herts, they have completely reorganised them, and adapted them, in the most practical and up-to-date manner, to the bromide process, and are ready to give careful and prompt attention to any orders entrusted to them.

**PHOTOGRAPHY AT A DISTANCE.**—A recent issue of the "Electrical Review" gives details as follows, and additional to those in the "B.J." of December 27 last, of the wireless method of transmitting photographs said to have been worked out by S. Sivelli. Whereas all methods so far suggested are designed for reproducing at the other end of the wire a ready-made photograph installed at the sending station, an interesting apparatus has recently been suggested by S. Sivelli, in "l'Elettricità," for the purpose of reproducing at a distance the optical image of a photographic objective.

The sending apparatus consists of an ordinary photographic camera, the sensitive plate of which is replaced by a plate made up of a network of small selenium cells, insulated from one another and communicating with a constant source of electricity, the negative terminal of which is connected to earth. From each of these selenium cells there starts an insulated wire, dipping into a small mercury vessel arranged on a horizontal plane. There are thus as many mercury vessels as there are selenium cells. These vessels are arranged round the circumference of a circle, round the centre of which rotates a metal index operated by clockwork, which, with a point attached to its end, will come into contact successively with each of the mercury vessels. This index communicates with a wire connected to the receiving apparatus, and insulated from the remainder of the outfit. The apparatus is to be worked in the following manner:—

After adjusting the focus for the image to be reproduced, the circuit is closed, and the index, having been set working, will traverse, one after another, the mercury vessels corresponding to the respective selenium cells.

The electric current from the battery will traverse the selenium cell actually in communication with the metal index, and, according to the more or less considerable action of the illumination on that cell, will undergo a more or less considerable alteration in intensity. These alterations in current intensity, corresponding to the illumination of each of the selenium cells, are thus successively transmitted to the receiving station, there to be reconverted into variable light intensities.

The receiving apparatus may be of various kinds; the one suggested by Sivelli is based on the following principle:—A cylinder performing a translation and a rotation is surrounded by a sheet of white paper, at a short distance from which a style communicating with an electro-magnet is arranged. If everything be adjusted in order to eliminate any variation of current intensity as long as the luminous intensity in all the selenium cells is the same, each current closure will

result in the production of a dash of more or less intensity, according as the selenium has been acted upon more or less strongly. The sheet of paper will thus be covered with a set of dashes, reproducing with greater or less approximation the optical image produced by the photographic objective.

The method thus outlined is obviously a purely hypothetical one. To produce an image at the receiving end that shall be coherent enough to be intelligible, the number of cells would have to be at least 1,000 to the square inch; and unless vastly more sensitive means than selenium cells can be devised for converting the variations of light intensity into variations of current strength, the idea seems impossible of realisation. Enormous difficulties would also be experienced in connection with the synchronising of the receiving and sending apparatus.

We, however, by no means despair of the invention of a device highly sensitive to the action of light, and we should not like to stigmatise the idea as beyond the region of ultimate possibility.

**KAISER'S POSTCARDS.**—Three picture postcards by the hand of the Emperor have just been published. One is a reproduction of a picture of a sea battle painted in 1895. Then there are two scenic designs for the Burggraf of Nuremberg tower, in romance style, signed "Wilhelm R.I., architect, 4-7-1893," and a couple of designs for regatta prizes. All bear autographic descriptions by his Majesty. Large orders for these cards are said to have been received from England, one firm alone having asked for 30,000 of them. Another proof of the Emperor's many-sided activity will shortly be laid before the German public in the form of photographs of Corfe Castle, taken by his Majesty during his recent residence in England. They are to be shown on a screen at a lecture by the architect Bodo Ebhardt on English and German castles.

### MAGIC MIRROR EFFECTS.

To the Editors

Gentlemen,—Mr. Levy's letter in your issue of January 10 is, I fear, based on a misapprehension. Though I discovered the deformation of glass plates under the suction of pneumatic holders by the appearance of Newton's rings when coating the plates with collodion, yet in the later optical proofs of actual deformation no collodion at all was used. If divergent light from a lantern is reflected by an ordinary uncollodionised mirror held by a pneumatic holder, the proof of cup-shaped deformation in the region of the holder is eloquent in the reflection.

What, then, for Mr. Levy's "explanation," depending, as it does, on temperature differences causing unequal rates of evaporation of the collodion solution, an explanation based on a non-existent factor? It is not likely that the readers of "Nature" (to which journal my letter was in the first instance addressed) would have permitted my explanation to pass without comment if it had not been the correct one.—Yours faithfully,  
DOUGLAS CARNEGIE.  
Blackheath, London, S.E.

### PORTRAITURE WITH MERCURY-VAPOUR LAMPS.

To the Editors.

Gentlemen,—I am sorry I did not see Mr. Henderson's letter in time to reply to it in this week's issue of your "Journal." With regard to the eight arc lamps which Mr. Henderson's friend has in his studio, I presume these must be open type lamps which are quite out of date for photography, as the light is not of great actinic

value. I do not know of any studio at the present time using "Westminster" enclosed lamps where more than two are used, the necessary "diffusion and dispersion" being obtained by suitable screens and reflectors. Some years ago we supplied four lamps to almost the first studio fitted up with this type, but I believe never more than three of them were used at one time. For cinematograph photography, of course, a larger number are required.

With regard to the current consumption, it is quite true that Mr. Hewitt gives the figures that Mr. Henderson reproduces, and I willingly admit that Mr. Henderson cannot reasonably be blamed for copying them. If, however, he had disclosed the source of his information when first mentioning these figures I could have put the matter right. The particular lamp used for the Mansion House portraits was one of our earliest No. 114 type, and was made to take 30 amperes on 200 volt circuit, corresponding to 6 units per hour. The latter figure given by Mr. Hewitt of 10½ units per hour must, however, be a mistake; few of these big-current lamps were made, as we found it unnecessary to use a larger current than 15 amperes on 200 volts. This is our standard No. 114 type lamp, the consumption per hour being 3 units, as I before stated. We had Mr. Hewitt's article reprinted, with his permission, exactly as it appeared in the "Journal," because it gave valuable information on points which we were constantly being asked about and were not always able to answer.

I am rather surprised that Mr. Henderson still attempts to justify his instructions re "Installing Lamps." I should have thought that in the interval he would have submitted the remarks to some electrical friend who would at once have told him, as I did, that they have no meaning whatever.

Mr. Henderson says he has "confined himself to facts, which in all cases were proven," and "that he has fully justified all his original statements." Well, I am pleased to hear that he is so satisfied with himself, and am quite willing to leave it to your readers to decide these points.

I was interested to find a letter from Mr. T. E. Staggs on the same page as Mr. Henderson's letter, and this really seems to answer some of his assertions better than I can, and to clearly refute his original statements in depreciation of arc lamps. We have many similar letters from photographers, clearly showing that no special skill is required, as Mr. Henderson would have us to believe, and no one with ordinary intelligence need be afraid of investing in suitable arc lamps for their photographic work.—I am, yours faithfully,  
J. O. GIRDLESTONE.

Westminster Engineering Co.,  
Victoria Road, Willesden, N.W.

### DRYING NEGATIVES WITH SPIRIT.

To the Editors.

Gentlemen,—Some observations I made about a year ago on the phenomenon referred to in your "Ex Cathedra" notes in last week's issue (January 10, pp. 17 and 18), namely, the milky appearance often found in negatives dried with the aid of methylated spirits, led me to what I believe to be a reasonable explanation of its cause.

I found that practically pure spirit, free from any mineral oil, gave rise to the phenomenon that if the spirit be changed two or three times and the negative left in the last bath for a considerable time (quarter to half hour), the milky appearance occurs while the negative is still in the bath; indeed, it is quite easy to turn the whole film white by reflected light by prolonged soaking in spirit. As you state, the opalescence instantly disappears on wetting the film, and does not return on spontaneous drying.

The explanation I offer is that the honeycomb or sponge-like structure of the fixed gelatine film is preserved when the water is extracted from the film by means of spirit, and it is this structure which diffuses incident light, giving rise to the coalescent appearance. In normal drying, of course, the cavities formerly occupied by the haloid are obliterated by the collapse and coalescence of their walls.

I hope to find time shortly to put this idea to a proper examination by the aid of the microscope.—Yours faithfully,  
F. F. RENWICK.

P.S.—It follows directly from this explanation that it is undesirable

to push spirit-drying to the limit, but always to finish with a bath containing 10 or 20 per cent. of water.

Norland House,  
Avenue Road, Brentwood.

### A TELEPHOTO CALCULATOR.

To the Editors.

Gentlemen,—In reference to the recent article by Mr. A. Lockett in "The British Journal of Photography" for December 20, 1907, on "Graphic Telephoto Calculations," I am sending you a chart which I drew up some months ago and found most useful when working with a telephoto lens in the Alps last summer. By its aid

I could immediately calculate the exposure, knowing the equivalent stop in use.

The method of constructing the diagram is as follows:—

Let  $x$  be the magnification and  $a$  the constant focal length of the negative lens, then  $y$  the camera extension is given by the equation—

$$x = \frac{a}{y} + 1$$

and my diagram is nothing else but the graphic representation of this equation. As it is an equation of the first degree it is repre-

sented by a straight line, of which it is sufficient to fix two points. This is done at once by taking  $x=0$  when  $y=-a$  and  $y=0$  when  $x=1$ .

I proceed then as follows: On a horizontal line as abscissæ I set out, to any scale convenient according to the size of diagram required, the magnifications starting from zero, one of the fixed points is given at once,  $x=1$ ,  $y$  being nil. Then through the point  $x=0$  I draw a perpendicular on which I take below the line a distance  $0-a$ , equal to the focal length of the negative lens in inches

and fractions, also to any convenient scale. That being done, there remains but to produce the line  $-a1$  right through the diagram. Then  $0-a$  being, to scale, the focal length of the negative lens, there remains but to divide the vertical in inches and fractions to the same scale, starting from zero (not from  $-a$ ), to have the extension for a given magnification.

Now for the right-hand part, viz., the equivalent stops. These are equal to the stop in the positive multiplied by the magnification. I adopt the oblique line just drawn as representing  $f/8$  in the positive, so that where the vertical 2 meets this line will be  $f/16$ , where the vertical 10 meets the oblique line is  $f/80$ , while where the vertical 0 meets the oblique line (that is at  $-a$ ) the value will be  $f/0$ , so on the vertical 10 I take a distance below the abscissæ  $-a$  and divide into 80 parts the distance between that

point and the intersection of 10 with the oblique line  $f/8$ , and so construct that scale. So far we have the equivalent stops for  $f/8$  in the positive. For other stops I proceed as follows: I find a vertical (between  $3\frac{1}{2}$  and  $3\frac{3}{4}$  in my diagram) in which the distance between  $-a$  and the oblique line  $f/8$  counted along the vertical is an exact multiple of eight (in this case 2 inches = 8 times  $\frac{1}{4}$  inch), and I subdivide that vertical in  $\frac{1}{4}$  inches, which I number 3, 4, 5, etc., and which represent the stop value in the positive lens. Drawing lines across the diagram from the point  $-a$  to any of these divisions gives the corresponding lines to the given stops. In this case I have only drawn four,  $f/6/8$  (maximum aperture I can obtain),  $f/8$ ,  $f/11$ , and  $f/16$ , but any other could be put in. To find, say, the stop equivalent to  $f/11$  with four magnifications it is only necessary to follow the vertical 4 till it intersects the oblique line  $f/11$ , and follow to the right from that point where on the scale already made will be found the value  $f/44$ .

I have added further to the right a scale corresponding to the relative exposures for  $f/8$ , as that is the aperture for which many of the exposure meters are made; for instance, if  $f/40$  is the relative aperture the exposure will be twenty-five times longer than it would have been for  $f/8$ . This scale needs no further comment.

This explanation is far more complicated than the thing itself.

I hope it may prove useful to other workers with the telephoto lens. I wish some writer would make some definite statements as to correct exposure, the Watkins actinometer test near the camera being quite useless for a snow-clad peak twenty-five or even fifty miles away, as was Mont Blanc, from Leuk, and I had to climb 7,000 ft. a second time with all my tackle because my first attempts were under-exposed on following the advice given by an Ilford exposure meter. However, I was successful the second time, getting a splendid negative of the Weisshorn.—Yours faithfully,

340, Hungerford Road, Crewe.

A. THOMAS.

## Answers to Correspondents.

\**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*

\**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

\**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*

\**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

Miss D. Inman, 18, Lindley Road, Bradford, Yorks. *Photographs of Miss L. Holmes and Miss V. Parker.*  
T. Kirkman, 34, Top-o'-th'-Wood, Heywood, Lancashire. *Photograph entitled, "A Country Seat in Picturesque Lancashire."*

M. E. M. AND CO.—We cannot say for certain, but you might try in Leeds, Reynolds and Branson, 14, Commercial Street; in Newcastle, Godfrey Hastings, 27, Ridley Place; and in Bradford, Riley Bros., Colonnade, Westgate. A London firm which would no doubt do the work is J. Williamson and Co., 25, Cecil Court, W.C.

DEVELOPERS.—1. Could you give me a good formula of iron-citrate developer to keep in powder? Also, is "amm. cit. iron" any use in making developers or sepia toning?—F. S.

1. The Valenta pyro-caustic developer, given on p. 792 of the "Almanac," is very similar in behaviour, and is cheaper. But it is suitable only for negatives. For positives a substitute is sold by The Tress Co. 2. Potass. oxalate,  $2\frac{1}{2}$  oz.; potass. citrate,  $2\frac{1}{2}$  oz.; ferrous sulphate,  $1\frac{1}{2}$  oz. Mix and dissolve for use in 40oz. of water. The citrate of iron and ammonia of the shops is a ferric salt, and of no use as a developer.

LIQUID BACKING.—Will you kindly tell me formula of a red liquid backing to prevent halation?—N. PIKE.

Asphalt, dissolved in chloroform or pure benzole, makes a very good backing. A red mixture consists of 2 per cent. collodion, 300 parts; linseed oil, 4 parts; 50 per cent. ammonia solution in alcohol, 100 parts.

AUTOCROMES.—M. C. Gravier, in his recent letter, states that after adding sulphuric acid solution to developer the rest of the operations may be done in daylight. I thought it was essential that the plate should have at least half a minute in "C" before seeing the light. (1) Will you kindly explain why this is not necessary? (2) Has the plate to be rinsed after the bisulphite solution? He does not mention it, and I cannot understand why intensification and fixing are not necessary with his method. (3) Shall be glad for any light you can throw on it.—AUTOCHROME (Bray).

(1) Provided the developer in the plate is acidified, the plate may be exposed to weak actinic light. (2) Yes, a brief wash. (3) The silver bromide left in the film has a rather pleasing effect. Try the process, and you will see for yourself. We have an Autochrome before us made in this way.

PROF. NAMIAS' HARDENING FIXING BATH.—The formula is not quite clear to me. Is the best one as follows: Equal parts of a 1.5 per cent. solution of chrome alum and a 50 per cent. solution of hypo, to which 2.5 grammes of sodium acetate solution were

added for each 100 ccs. of the combined solution of the first two? What is the strength of the sodium acetate solution? It is not given, and I did not know that sodium acetate is itself a liquid, and if it is why is the proportion given in grammes and not in liquid measure?—AUTOCHROME.

The solid (cryst.) acetate should be dissolved—best in the hypo solution.

COPYRIGHT.—I have been given a photograph, with permission to reproduce postcards and to sell them. Can I register my reproduction? I do not know whether the photograph is copyright or not, although I got permission from a very good authority very closely connected with the actual photographer.—F. H. H.

You cannot, and you have no right to, reproduce the photograph without the permission of the proprietor unless, which is not likely, there is no copyright subsisting in it. Unless you want to incur penalties for infringement you must make it your business to discover the owner of the copyright. If the photograph is of a person who paid a photographer for taking it the copyright is the sitter's, but in any other case it is most probably the photographer's.

COMMON TINTING.—Could you inform me what methods and kind of colours required to reproduce tinted photographs as sample enclosed, whether water or oil colours are used? I understand how to put the celluloid on same, as I have tried your receipt re same out of your book.—ALFRED DEWSNAP.

Sets of colours, specially made for this kind of tinting, are sold by all the large dealers in photographic materials. They are water colours, or, rather, dyes, soluble in water.

INTENSIFIER.—(1) *re* chromium intensifier, p. 800, "Almanac." Can any other developer than amidol be used—say pyro-soda? Will it keep? (2) My studio is some distance from residence, and I find great difficulty in varnishing negatives by usual methods. Would a cold varnish, composed of part gold size and part benzole, give a little protection and not interfere with retouching, or can you give me a better? (3) Is benzine (highly rectified) the same as benzole? I asked for some of the latter at a chemist's, and they said it was the same as the former. The carriage regulations prohibit me from getting a small quantity from London.—WEEDEE.

(1) Developers without liability to stain may be used; on this account pyro should be avoided. A neutral or almost neutral developer, such as amidol, is better than one containing the usual quantities of alkali. (2) A mixture of Japanese gold size (1 part) and benzole (2 parts) forms a slow drying but excellent cold varnish, and the surface takes the pencil well. (3) Benzole and benzine are identical, a coal tar product of formula  $C_6H_8$ . "Benzine" is a light mineral naphtha, that is, a very light pure paraffin oil.

COLOURING PHOTOGRAPHS.—I should be glad if you could tell me of a good book on colouring photographs in water-colours, and where obtainable.—D. W. ROSS.

The best is "The Art of Retouching Negatives and Working-up and Colouring Photographs," by R. Johnson (Marion and Co, 2s.).

DIODES.—Dorrett and Martin, 16, Belle Vue Road, Upper Tooting, London, S.W.

GLAZING P.O.P.—The enclosed half-dozen gaslight cards, unexposed, are a sample of 1,000 cards received from the —. I have recently had 2,000 cards from them which worked very satisfactorily. These cards we cannot glaze in the ordinary way; by that I mean by hardening in about a 5 per cent. solution of formalin and squeegeeing down on glass. The difficulty we have is, after they have been put down on the glass and stood aside to dry, in a little while they begin to leave the glass in small patches, and when they are stripped the results are as per enclosed card. We have inquired of the firm the cause and sent them a card or two, and they say they had no difficulty whatever in glazing them. These were cards we had tried two and three times. They said by simply soaking in plain water and putting them down on the glass they remained perfectly in contact until stripped.

We have no difficulty with other make of cards worked side by side with them, but these we positively cannot glaze. I would say we do not consider ourselves by any means novices at this work, as during the last two years my ledger account shows we have had over 34,000 cards through our hands, all treated in

this manner. If you will kindly try these and report on same in your columns shall be obliged.—H. P. R.

We have tried the cards, using, instead of formalin, a 5 per cent. alum solution for five minutes. The results, as you will see from the cards sent you, have stripped well with a uniform glaze. We suggest that formalin over-hardens the surface.

**FORMULÆ.**—1. On page 43 of the "B.J." for January 18, 1907, is an article on "Standard Formula," but as I am not good at figures, and it is not quite clear to me, could you give me a mean formula in simple figures for, say, 10 oz. or 20 oz., or whatever quantity of water you find to suit? The mean is given over the page 44 in fractions, which I am not clear about, also amount of water not stated in that column. 2. On page 5 of "B.J." for January 3 is formula for alum-hypo by Professor Namias. No. 13 reads as follows:—

(13) Chrome alum solution .....	1.5 p.c.	...	50 ccs.
Hypo solution .....	60 p.c.	...	50 ccs.
Sodium acetate solution.....	—	...	2.5 gms.

What strength of solution is sodium acetate solution as given? But how can it be in solution when it is given in gms. as above? Kindly give me it in simple figures.—THISTLE.

1. We presume you require the formula at foot of page 43 in British measures. It will read:—

Pyro .....	60 gr.
Sulphite .....	1 oz.
Carbonate .....	400 gr.
Water .....	20 oz.

2. The word "solution" occurs in error. Solid sodium acetate ( $\frac{1}{2}$  grammes) should be used.

**FADING COLOURS.**—I should be extremely obliged if you would help me in the following matter:—I have been doing some silver prints as miniatures and tinting them with albumen colours, but find that some of them turn yellow and fade (the colours, not the prints) after a few weeks. Is this owing to their not being protected from the atmosphere by celluloid, or are the colours at fault? 2. Where can I get suitable celluloid for covering? 3. How is it made to adhere? 4. Are ordinary aniline dyes dissolved in water suitable for tinting?—MINIATURES.

1. If you find the colours mentioned to fade, we should advise you to try another make, though we have not heard of their fading before. 2. Messrs. Fallowfield supply celluloid for the purpose. 3. The print is immersed in methylated spirit, drained, and then rolled slowly over with a heated roller made for the purpose, when the two will adhere. Fallowfields also supply rollers and plates specially for the purpose, with directions for doing the work. 4. Yes, some of them. But you had better get those specially supplied for the purpose. They may be had from all the large dealers.

**STUDIO QUERY.**—Kindly inform me in your "Answers to Correspondents" whether the room described below would be a suitable studio for professional portraiture:—Length, 21 ft.; breadth, 12 ft. 6 in.; height, 8 ft. 6 in.; side light only: height 7 ft., breadth 12 ft. The fact that the light is only a side one is the main point on which I want information, as I am aware that 21 ft. is rather short.—SIDE LIGHT.

The room can be utilised as a studio, but, as you are aware, it will be short for professional purposes. The side light will answer, but we should advise you to make it a couple of feet higher if possible. We should also advise you to paper, or colour, the dark side with a light colour, so as to get a good reflected light on the shadow side of the sitter.

**PERPLEXED.**—If your commission was paid weekly we should say you were entitled to a week's notice. It certainly appears that you have been shabbily treated, and a county-court judge would, we think, take the same view of your case. It would have been better if you had had a written and stamped agreement with the firm.

**F. B.**—It is difficult to give precise rules in these cases, but one-half ounce to an ounce at least, we should say.

**COPYING.**—Will you kindly give me information on the following:—I have got a half-plate field camera, double extension, and fitted with a Beck symmetrical lens, made by Tyler, and I wish to do

some copying with it, but am unable to get more than a midget copy from a cabinet portrait. I do not want to part with the camera if I can help it, so will you advise me which is best to do? I am a cripple, and cannot afford to go to much expense. I want to be able to copy from a cabinet to the same size, if possible.—E. W. STUBBS.

If the camera racks out to double the focal length of the lens (as implied by your description of double extension), it should be possible to make a copy same size as the original. Rack out camera to full, and see what you can get; otherwise you had better make a temporary extension tube, of cardboard even, or get a so-called copying lens-attachment, a cheap form of which is sold as the Planiscope.

**F. S.**—Mr. E. W. Foxlee, 22, Goldsmith Road, Acton, W.

**TONING BROMIDES.**—1. I enclose a sulphide-toned bromide card. Could I obtain a warmer tone by this bath (page 1,059 of "B.J. Almanac," 1907)? 2. Would the following do better (I want a ruddy P.O.P. tint)?

A. Ferricyanide potash .....	77 gr.
Water .....	17 $\frac{1}{2}$ oz.
B. Uranium nitrate .....	77 gr.
Water .....	17 $\frac{1}{2}$ oz.

mixed in equal parts before use. If so, how many could I tone at one time, and would they want bleaching first, and how long might they last? 3. In a back number of the weekly "B.J." you gave a recipe for an alum hypo bath with nitrate of silver. Should I bleach prints first for this bath, and would it give a brighter warm tone?—OPERATOR.

1. Almost any sulphide toning formula should give you a warmer tone than that of the miserable specimen. 2. The uranium formula would give you a red, but not a very bright tone. The solutions A and B are mixed and the print toned in it. The results may last a year or two if properly done. A better process is that "Sulphide plus Gold Toning" on page 793 of the 1907 Almanac. 3. No, the silver is only for bringing the bath into working condition. The tones are purplish brown.

**STAINED PRINTS AND THE COLD WEATHER.**—Enclosed please find a few unmounted prints. You will notice they are all mottled with yellow stains, for which we cannot account. We use the — P.O.P., but these were made from a batch received a week ago, and we have never had any trouble with it before. At first I thought that the stains might be due to the prints being "scamped" in the washing, but my printer, who has been with me a long time, assures me she washed them as long as usual. Do you think this batch of paper is at fault?—C. H. J.

We do not. The stains are clearly due to the prints not being perfectly fixed. That is obvious by the fact that some of them show a clear mark where two have been allowed to stick together while they were in the hypo solution. In cold weather the complete fixation of prints takes a much longer time than it does in warm—a matter that is often overlooked by printers. At this time of year care should be taken that the temperature of the fixing bath is not less than 60 deg. or 65 deg., then fixation will be complete in the usual time.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Japanised carbon prints on ceramic ware are dealt with under the heading of "Profitable Forms of Carbon Printing." Their preparation calls for no special skill, and the results are highly effective. (P. 60.)

A lengthy paper on the properties of agar in emulsion-making by Messrs. W. F. Cooper and W. H. Nuttall occupies a considerable portion of our space. (P. 62.)

Mr. Cooper has taken out a patent for an agar P.O.P. (P. 70.)

A non-slip tripod shoe and a lantern-slide storage box are among other patents of the week. (P. 70.)

We discuss a few of the considerations which should make the photographer pause before insisting too strongly on the "professional" character of his occupation. (P. 59.)

Two cases in which verdicts were given to persons claiming the return of photographs appear under "Commercial and Legal Intelligence." (P. 73.)

Dr. C. E. K. Mees contributes a brief review of the work of Mr. J. Sterry, to whom the Royal Photographic Society has awarded its Progress Medal. (P. 61.)

A recent action with reference to daylight development in which the Kodak Company were successful is reported on page 73.

Some fallacies regarding the re-development of negatives are mentioned on page 58.

Some further notes on the dewing of lantern slides which point to the nuisance being avoidable by the proper construction of the lantern will be found on page 55.

M. Reeb gives directions for the making of stock pyro solutions for use in pyro-soda development. (P. 68.)

One or two reminders as to the drying of negatives in cold weather and the economy of properly warmed workrooms are mentioned on page 59.

## EX CATHEDRA.

### Pyro Soda.

On another page an interesting article by M. H. Reeb will be found dealing with the pyro-soda developer. It will be noticed that his formula is reminiscent in a curious fashion of two different formulæ that formed the subject of discussion in our pages some months ago. It will be remembered that we then advocated keeping the carbonate in a separate solution, and putting the sulphite after neutralisation into the pyro bottle. M. Reeb neutralises the sulphite and then adds it to the carbonate, though the object of so doing is not at all evident. It is stated that the purpose of neutralisation is to eliminate the carbonate that is always found with so-called "pure" sulphite, but the curious feature is that this neutralisation of the carbonate is immediately followed by the addition of a very much larger quantity of that alkaline salt. It should be observed, however, that the process of neutralisation described by M. Reeb does not, as a matter of fact, eliminate all the carbonate. He uses phenolphthalein as an indicator, and as this is neutral to bicarbonates the pink tinge on the paper fails to appear just when the carbonate has been converted to bicarbonate, which product will only be eliminated by the addition of a double quantity of acid. The final result of M. Reeb's method is therefore a solution containing sulphite, carbonate, and bicarbonate. He does not claim any special keeping qualities for this solution, and the advantages of the peculiar method of preparation are not very clear. It is interesting to note that a practical authority like M. Reeb still believes in adding carbonate to counteract under-exposure, and pyro solution to remedy over-exposure.

### Dr. Mees and Spook Photography.

Any one possessed of the gift of "reading between the lines" can be trusted to make startling discoveries, so we need not be so very surprised to find that Dr. Mees is unexpectedly credited with the production of a plate eminently suited to photograph spooks, and ghosts, or astral beings, as they are now styled in the most refined spiritualistic circles. According to a contemporary, Dr. Mees recently made a communication to the R.P.S. to the effect that by means of a dry plate specially sensitised with dicyanin it was possible to photograph forms floating about in the air which have hitherto never been either seen or photographed. We have no recollection of such a communication, and cannot find it in the R.P.S. Journal, but possibly it was discovered by photographing the report of what Dr. Mees did say upon a dicyanin plate. Anyway, it is now down in obvious print, and Dr. Mees has achieved a public reputation that we feel he does not deserve and fear he does not wish for. In any case, we are afraid the plate will not do all that is claimed for it, seeing that it is specially sensitised for the red, while spooks are generally supposed to be of an ultra

violet hue. We may, however, be wrong on this point, and perhaps the gifted person who heard or read Dr. Mees' communication has good reason for knowing that red is the predominant colour in the astral world.

\* \* \*

#### Exposure With Telephoto Lenses.

In a letter by Mr. A. Thomas, published in our issue of January 17, the writer expresses a wish that someone would make some definite statements as to correct exposure with the telephoto lens, as he has found ordinary tests with actinometer and exposure meters quite useless when dealing with very distant objects. As telephoto work on very distant objects generally means a high magnification and a correspondingly small effective aperture, it seems likely that the trouble is due to an effect similar to that which upsets our calculations in autochrome work. When dealing with either light of small intensity, or plates of very low speed, it is evident that ordinary rules of exposure break down to some extent, and that following those rules rigidly leads to effects of under-exposure. Mr. Thomas's statements serve to emphasise what we have suggested in another paragraph, viz., that it is very desirable to give further consideration to the matter of exposure with the view of finding some method of getting over these difficulties.

\* \* \*

#### Cautious Free-Enlargement Firms.

The report of a case tried in a Yorkshire county court last week, which appears under "Commercial and Legal Intelligence," is an indication that the free-enlargement canvassing firms are getting uneasy at the prospect of coming within reach of the law. As our readers know, sentences of terms of hard labour have been passed on canvassers who on the pretext of something for nothing have induced ignorant people to pay them small sums, alleged to be for the carriage of the promised enlargements, which, it is often represented, is being made by way of an advertisement. A case of this kind was reported in our issue of January 10, and now we find another of the "art companies" turning back from its game of bluff at the door of the county court. They had threatened in two cases to sue for payment of frames which had been delivered with "free" enlargements, but when the case came on begged for an adjournment on the ground of illness of witness. But as they declined to pay the costs of the day into court no adjournment was granted, and the judge gave a verdict for the defendants in each case with costs.

\* \* \*

#### Re-development.

The redevelopment of negatives and prints is now very frequently employed for various purposes; sometimes for intensification, and sometimes to clear stains or improve colour. A great deal has been written on the various methods, and much time has been devoted to their investigation, so it is a little surprising to note the frequent errors that various writers still make in regard to the subject. For example, we have just read that a print bleached in potassium ferricyanide and potassium bromide should be exposed to sunlight for a time before development. Yet it has been pointed out on numerous occasions that such an image requires no exposure to render it developable, and that too much exposure will often make it undevelopable. As the bleached image does not consist of normal silver bromide, but of a readily developable "photo-bromide," the exposure is a quite unnecessary risk. Again, in another article, we are told that if an image is converted into a chloride by the use of a bath rich in chlorine, redevelopment produces intensification, because silver chloride readily yields a much more opaque image than silver bromide. The last statement

has no foundation in our knowledge, and, as a matter of fact, some experimenters have expressed the opinion that bromide yields the blacker image. Generally, the difference is practically inappreciable, and in any case the condition of a bleaching bath "rich in chlorine" is one that is usually quite fatal to intensification at all. Free chlorine in the bleaching bath gives normal silver chloride that requires exposure. To produce intensification the production of the "photo-chloride" seems to be necessary, and this is not formed in the presence of chlorine only in that of various compounds of chlorine, such as chlorides, the action of which is very indefinite. Any kind of bleaching bath rich in either chlorine or bromine is to be avoided if intensification is desired.

\* \* \*

#### Screens for Newspaper Half-tones.

In our issue for January 10, p. 28, reference was made to Richter's process for making coarse half-tone cuts. Further notes on this process have recently appeared in the "Photographische Korrespondenz," illustrated by some very striking results on coarse news paper, with forty-five lines to the inch in the lights and ninety lines in the shadows. Comparative cuts are also given on finer paper, with seventy-five lines in the high-lights and 150 in the shadows, and an ordinary half-tone, with 150 lines everywhere. The better drawing in the shadows and brilliancy of the compound illustrations are most marked. No further working details are given beyond those in our previous note, but it is suggested that the new process would be of considerable advantage in three- and four-colour printing. A company has been formed in Berlin to work the process.

\* \* \*

#### Dew on Lantern Slides.

Our previous note on this subject has already drawn some interesting information. We are reminded by a friend that the better slides are bound, the more certain are they to show moisture in the lantern. Badly bound slides, or ones with the binding partially torn off, seldom show the effect at all. He has further noted that slides that are liable to become dewed very soon become badly pitted and spoilt. This confirms what we suggested before, that the moisture is derived from the slide itself; that is to say, from the gelatine and paper. To roughly test this, we took a slide from a box in which it had lain for a very long time in a cold and rather damp room, and exposed it to the dry heat of a gas stove. With the cover-glass side held away from the heat, the slide immediately dewed all over on the inside of the cover-glass, just as much moisture being apparent over the black paper mask as over the gelatine film. On reversing the slide, with the cover-glass nearest the source of heat, which is, presumably, the position of the slide in a lantern, no dewing effect was apparent. If, however, the slide had been enclosed in a lantern, and so protected from cold air on the other side, the dewing might have taken place. To test this, we enclosed a slide in a printing-frame with the cover-glass exposed, and on heating both the frame and the cover-glass the dew again appeared, though not so rapidly nor to such an extent as when the heat was applied only to the image side. This experiment is suggestive of several things. First, that a desiccated and varnished gelatine emulsion slide bound up with dry non-absorbent binders and masks should not dew at all. Second, that as the effect is evidently due to the saturation of the film between the two glasses free ventilation between them is desirable. And, third, it also suggests that to produce the effect in the lantern the glass nearest the objective—that is, the slide itself—must be, if anything, slightly hotter than the cover-glass. This is rather an unexpected conclusion, but possibly the conditions may be fulfilled if there is freer

ventilation between slide and condenser than between slide and objective. We regret to find a slip in our previous note on this subject. While it is obvious that the air in the lantern is drier than the air in the room in the sense that it is very much farther from the point of saturation, yet it does not therefore follow that it contains less moisture. This is not a matter of much importance, seeing that it is impossible for the moisture on the slide to be derived from the air in the lantern unless the slide happens to be very much colder than the air outside the lantern. This, of course, cannot be the case if the slide has been kept in the room.

\* \* \*

**Drying negatives.** During the very cold or the very damp weather which we are likely to get during the winter months difficulties arise in connection with the drying of the negatives developed and racked in the early part of the evening. Possibly the warming of the studio and work-rooms is slackened off after four o'clock, when further sittings cannot be made, and by six or seven o'clock, when the negatives are set out to dry, the temperature has fallen maybe as low as 45 deg. F. If the atmosphere is really dry—that is, as dry as warmed rooms often are—the absorption by the air of the moisture in the gelatine films may proceed satisfactorily. It is, however, more than likely in many cases that the air is fairly moisture-laden, and so drying is very slow. Should the temperature fall below freezing-point markings on the film are almost certain to occur. In order to avoid any risk in this direction, and to ensure the negatives being ready for the retoucher first thing next morning—a most essential matter if proofs are to be promptly despatched—a drying cupboard should be arranged. A large air-tight box arranged as a cupboard with well-fitting door may be fixed up so that the racks of negatives will stand on perforated shelves within it. At top and bottom a 12-in. length of sheet iron tube should be fitted, the top piece as a chimney and the bottom piece to prevent a tiny Bunsen gas jet from coming too near to the wood of the cupboard. A current of warmed air will pass through the cupboard, and any trace of fumes from the gas will have no detrimental effect on the negatives. If preferred, the gas jet may be at the top of the chimney, thus drawing the air through the cupboard; fumes in the cupboard are avoided, and any risk of over-heating also.

\* \* \*

**Temperature of Workrooms.** We recently had a short conversation with a printer employed by a firm of photographers doing a considerable business, during the course of which it was mentioned that printing was done out of doors, and that the room used for changing and the toning of silver prints and development of platinotypes was totally unwarmed. During toning it was the practice of the unfortunate printer to light a small gas ring and haw his numbed fingers over it. Quite apart from the question of common humanity, on which it might not be well to let ourselves go, we think such parsimony in the matter of warming is very short-sighted policy. No one, however willing, can work well under such conditions. It is physically impossible to change prints deftly and quickly with half-frozen fingers, and during the bitter weather of the past month no smartness of movement is sufficient to keep the extremities warm when the changing and toning room is several degrees below freezing-point. Further than this, it is most probable that the waste of gold due to carrying on toning at such a low temperature is in excess of the cost of fuel for warming, provided a suitable closed stove or hot-water system were employed. It has long been recognised by our commercial friends in

America that attention to the welfare of employees is not an expense but a profitable investment, and in England many of our progressive firms give as much attention to the warming, lighting, and ventilation of their work-places as to that of their own residences. The greatest suffering is in small and unorganised businesses, where competition is most felt and expenses are rigidly kept down; but it cannot be too often pointed out that many supposed economies are false economies, and that the "penny wise and pound foolish" policy never will pay.

## SHOULD THE PHOTOGRAPHER POSE AS A PROFESSIONAL MAN?

We often hear from some of our good friends among portrait photographers of the exalted station which the noblest and the best of the photographic fraternity—our good friends would no doubt include themselves—should regard themselves as occupying. "Let us take ourselves as professional men," we are told, "and the public will accept our valuation of ourselves. Perhaps not now, but presently." Many of those who adopt this tone cannot for a single instant be charged with snobbery in the matter. They are perfectly candid. They are convinced that there is "more in" portrait photography when it is regarded as a profession than when it is conducted on the common principle of buying and selling. Willingly we give the devil his due because we would like to discuss—and possibly the reader may wish to discuss—whether such an attitude can be taken under existing conditions, and what it involves not only in the photographer's relations with the public, but in his relations with other photographers. For most certain it is that the assumption of professional dignity must be made simultaneously and concurrently with certain radical changes in the photographer's conduct towards both the public and his fellow photographers, or it at once becomes ridiculous in the eyes of those with any sense at all of social distinctions—certainly in the eyes of the people whom the photographer hopes to catch in his newly made nets.

We would not be thought to be taking the view that this exaltation of rank is not a very desirable thing from the financial standpoint. It may or may not be; there are poor professional men just as there are poor shopkeepers, and we doubt very much whether the ability to obtain money by painting portraits, prescribing medicines, or giving legal advice is actually different in kind from the ability to sell cheeses, or potatoes, or cabinet photographs at a profit. In any of these pursuits the man of genius will make or command a fortune and will earn the huge commissions of a Sargent or make a corner in cheese. But among the mediocre types in each class the difference is not important, and what applies to one applies pretty much to another. The question is—and apparently it is not definitely asked and answered by those who prescribe professional dignity as a panacea for the ills of a portrait business—can the so-called "professional photographer's" business be profitably reconstituted on the lines of the professions proper, such as the dentist's, the doctor's, the lawyer's. There are photographers who are quite professional in their methods, who announce their habitation as formally as the brass plate of "Messrs. Silk and Stuff, Solicitors," who never resort to a solitary line of advertisement, and whose other procedure is in accordance with the canons of "professional conduct." But such men would never pay a quarter's rent if their work was not so distinctive that people, having once seen it by chance, sought them out to commission them. Our professional reader will retort—and rightly—that that is a method of drawing people to his studio upon which he relies as much

as does the highly individual worker; yet he probably ignores the fact that the difference between his work and that of his competitors is insignificant compared with that between the good photograph of the average studio and the productions of the very few men who have found it possible to make their business semi-private. Thus we are forced to the plain common-sense view that a photographer is a tradesman just as an author is a tradesman, and both get on in precise proportion as they produce a saleable article and take the best means to secure the best price for it. If there are photographers who are able to conduct their businesses on the basis that they give to the sitters what they (the photographers) think best for them, the essence of their strength will be found, at any rate, equally divided between their work and their powers of handling men and women, even if the latter does not account for the larger proportion. Ordinary conditions cannot be held to apply to such men, who, to exist at all, must breathe the air of a metropolis. In the case of photographers, who perhaps are their equals, technically and artistically, but have not "a way with them," there is no evidence but what points to the studio as essentially commercial in character, a place for selling at the best price, and with regard to the same circumstances which have to be considered by the successful shopman. If this argument were not sufficient, the obligations towards those following the same occupation as himself, which are a part of professional conduct, might be cited in further proof of the present improbability of the photographer successfully living up to the standards which have been suggested. But any remarks on a possible creation of such a thing as photographic etiquette would take us beyond the space now at our disposal, and we must defer them until an early issue.

## PROFITABLE FORMS OF CARBON PRINTING.

### II.

In our last article we referred to the employment of Japanese vellum as a support of the carbon print and to the rich effects thus obtainable; and we were able to give directions for presenting in the finished prints the surface and texture of the vellum. We may now allude to a further application of carbon printing which deserves attention.

During the past year or two the fashion for photographic portraits in jewellery has been decidedly increasing. The cheaper kind are faced with celluloid, after the manner of the photo-buttons, but most of the better class are veritable ceramic photographs, where the picture is vitrified in enamel on a copper base. The production of these vitrified enamels is not a really difficult matter, but the process is one that has to be learnt and it necessitates the possession of a suitable muffle furnace for the firing in. This latter is not a costly affair, as only a small one heated by gas will suffice for small pictures, such as are required for jewellery and the like. But if we require ceramic photographs on a larger scale—say, plaques of ten to fifteen inches—a muffle of a much larger size becomes absolutely necessary. There is, however, a method of producing photographs on ceramic ware—enamels, porcelain plaques, tiles, etc.—quite equal in appearance to—and to all intents and purposes as permanent as—veritable ceramics. The method will give pictures in any colour, and allows of colouring or working up in monochrome, operations which become somewhat expensive when we have to do with "fired-in" pictures.

We have little doubt that photographers who care to make a feature of what may be termed imitation ceramics of a fairly large size, would find them a good line in their

business. When we now explain how the pictures are produced, it will be seen that the process is really a very simple one, especially to those who are accustomed to work the carbon process. It may be mentioned here that the process has more than once in past years been described in these pages; indeed some five-and-twenty years back formed the subject of a patent, though, if our memory serves us rightly, it did not go beyond the "provisional" stage. Possibly that was because it was introduced before its time, like many other processes which have afterwards proved valuable, if not to their inventors, to others who benefited by them.

In a word, the picture is a japanned carbon print on enamel, porcelain, earthenware, or other vitreous support. The procedure is as follows:—The carbon picture may be made either by the single or the double transfer method. On the whole, we prefer the former, as it is the least trouble. The porcelain or other vitreous support is first thoroughly cleaned, and is then coated with a solution made as follows:—

Nelson's No. 1 gelatine .....	1 oz.
Water .....	20 ozs.
Chrome alum, dissolved in 2 ozs. water...	20 grs.

The support is allowed to dry after this application, and is then ready for use. It is not necessary here to go into the working details of the carbon process, as most people nowadays are quite familiar with them. It is sufficient to say that the procedure is as usual, but we may add that it is desirable to employ a tissue that contains a large amount of pigment in proportion to the gelatine, so that in the japanning the varnish will be the better bonded to the porcelain plaque. The tissue, after printing, is squeezed on to the substratum plaque just in the same way as if it were on opal glass or single transfer paper, developed and alumed in the ordinary manner, and allowed to dry. If the double transfer method is employed, the image is developed on flexible support in the usual way and then transferred to the plaque. In this case the latter is coated with a solution made as follows:—

Nelson's No. 1 gelatine .....	1 oz.
Water .....	20 ozs.
Chrome alum, dissolved in 2 ozs. water...	12 grs.

It will be seen that at this stage our picture is a simple carbon print on a porcelain support. It has now to be japanned.

Japanning, it may be explained, is the application to a surface of three or four thin coatings of a hard varnish such as amber or copal, and the subsequent exposure to a somewhat high temperature for some hours, so that the successive coatings, so to speak, are welded together by the heat. A very suitable varnish for our present purpose is that sold by all high-class varnish makers under the name of "Pale copal varnish for stoving." The varnish—the first coating of which should be mixed with an equal bulk of turpentine—is thinly applied with a brush. In the subsequent coatings the varnish is used as it is supplied by the makers. When the first coating is thoroughly dry, and not before, a second is laid on, and when that is dry, another. Three or four, or more, will be required to get a surface like that on a highly glazed vitrified enamel. Should brush-marks show, they are of little moment, as they will spread and disappear as the coating becomes somewhat softened in the stoving. If there is a professional japanner in the photographer's neighbourhood he would probably execute this part of the work for a reasonable charge, as he will have properly constructed ovens or kilns for the purpose always in use. However with a little experience equally as good results may be obtained in the

ordinary kitchen oven. It goes without saying that while the successive coatings of varnish are drying the surface must be carefully protected from dust, for if any gets embedded in it it cannot afterwards be got rid of. After the last coating is thoroughly dry the plaque is placed in the japanner's kiln, or the kitchen oven, and kept at a temperature of from 140 deg. to 180 deg. F. for six or eight hours. In that time the varnish will have become as hard as the surface we have on the best tea-trays and similar japanned articles.

The surface of the picture is now polished, first with very fine pumice powder and finally with tripoli or rouge. We have now a picture which has all the beauty of a fine enamel, while it is as permanent as if it were actually "fired" into an enamel plaque. We are all fully aware of the extremely hard surface of japanned ware, and we also know the permanency of the carbon picture.

These pictures can, of course, be highly finished in water-colour or in monochrome, and they are exceedingly effective. That, however, must be done before they are japanned; the varnish will not interfere with the colouring in any way. We may here mention that if the pictures are coloured it is not advisable to gum up the shadows, as the varnish fulfils the same end, and it is not desirable to have more of a medium non-penetrable by the varnish than is actually required.

A word as to the mounting of the pictures: Those of small size, on the usual enamel tablets, can, of course, be fitted into locket, brooches and the like. A suitable mounting for the larger sizes, say six inches and upwards, on convex porcelain plaques, would be the ornamental gilded frames, now so general. Of course, the pictures require no glass as a protection, nor would it be desirable to have it.

## THE AWARD OF THE R.P.S. PROGRESS MEDAL TO MR. J. STERRY.

[We announced last week the award, by the Council of the Royal Photographic Society, of the Progress medal to Mr. John Sterry. The following note by Dr. C. E. K. Mees may serve as a useful referendium to the earlier work of Mr. Sterry on solarisation and the latent image.—Eds. "B.J."]

THE award of the Progress Medal of the Royal Photographic Society to Mr. John Sterry will be judged by all as the just reward of much unostentatious hard work done by a real amateur, simply from love of knowledge. Without special scientific training, Mr. Sterry has devoted a very great capacity for scientific research to the elucidation of photo-chemical problems. He had for some time been experimenting in a tentative way with photographic plates, when in 1890 Messrs. Hurter and Driffield cleared the whole horizon of photo-chemistry by the publication of their notable paper "Photographic Investigations," and he was quick to see the importance of the methods of research which they had employed, and of the principles which they maintained. Mr. Sterry threw himself heart and soul into the defence of the new scientific basis of photography against those who appeared, judging by their publications at that period, to desire to prevent photo-chemistry being put on any rational basis. The opponents of Messrs. Hurter and Driffield, with few exceptions, did not offer any positive suggestions, their criticism was purely negative, and they did not seem to have realised that inaccurate work, or only partially accurate work, 's better than no work at all. Mr. Sterry fought manfully for the cause, and was the means distinctively of introducing the speed-testing system advocated by Messrs. Hurter and Driffield into commercial life by his influence with some manufacturing firms.

The Progress Medal of the Royal Photographic Society, however, could scarcely be awarded for controversy, however much needed or able, but Mr. Sterry has distinguished himself quite as much by his own researches as by his advocacy of the principles held by Messrs. Hurter and Driffield. In 1895 he published a paper on "Standard Plates, and Some Causes of Apparent Alteration in Rapidity," the true value of which has even yet not been fully appreciated. Among other matters in this paper was discussed the effect of moisture on the sensitiveness of plates, and some of the views expressed have an important bearing upon the cause of solarisation. These views are, in some respects, opposed to those of Messrs. Hurter and Driffield, a fact which is noteworthy as showing that Mr. Sterry has been no slavish or uncritical follower. He took a considerable part in the controversy on development which raged in 1895 and 1896, and in 1898 he published a paper on the "Two Latent Images (Organic and Inorganic), and Development after Fixing,"

in which he demonstrated the nature of the image which is left when an exposed plate is fixed, and can be developed by the use of a reducing solution containing silver, i.e., by what is known as physical development.

Other small researches on the development of gelatino-chloride paper and the reversal of the photographic image followed, and in 1904 Mr. Sterry published an exceedingly important paper on the action of chromic acid on the latent image, in which he expressed the opinion that development is separable into primary and secondary actions, the first action being the development of the exposed silver bromide, and the second the intensification of this exposed silver bromide by silver bromide dissolved from adjacent portions of the unexposed salt.

This theory has a most important bearing on the whole theory of development, and it was attacked in 1906 by S. E. Sheppard and myself. Mr. Sterry replied to our objections in a paper in 1907 on "The Actions of Exposures upon the Development of the Latent Image."

In polemical matters Mr. Sterry has invariably shown the true spirit of a scientist; he has, in his research work, been a true amateur, working for the love of the subject and for the love of truth, and has never allowed prejudice or preconceived opinions to prevent him from accepting with careful, frank, and fair criticism any new fact or theory which might be brought to his notice, however opposed it might be to conclusions previously formed by him.

The practical results arising from the 1904 paper were of importance. Mr. Sterry worked out a method of improving the rendering of bromide paper when printing long scale negatives having a great range of contrasts, by soaking the paper after exposure in a solution of potassium bichromate before development.

For the last two or three years Mr. Sterry's activity in research has been somewhat diminished by reason of domestic sickness, but there is every reason to hope that he will shortly be as active as ever; he is, indeed, preparing another paper on solarisation which promises to be at least as important as those which he has already published. It is to be hoped that for many years Mr. Sterry may be able to continue the investigations which the Royal Photographic Society have recognised by the award of their valued Progress Medal.

C. E. KENNETH MEES.

## AGAR-AGAR IN EMULSION MAKING.

(A Paper read before the Royal Photographic Society.)

THE work of which I am about to speak has been undertaken by scientific men who are not practical makers of material for photographers. Papers have been mostly coated by hand; only quite recently has a small machine been made; the plates which will be shown were coated by men who had only had a small experience in wet-plate collodion work; and a medium new to the purpose was employed. On this account, I must ask that certain allowance be made for the quality of the results which we show. The work has been of a scientific, rather than of a technical, character; but I trust that we shall show in the sequel that the results obtained will be of practical value.

### History.

When commencing the work, we could obtain no data upon which to found our experiments, so that we have been working somewhat in the dark; but we believe that our results will form the basis and starting point for those who take up the study of agar-agar.

The first notice we have of agar in Europe, is in a paper by Payen ("Comptes Rendus," 49, 521), in 1859. He mentions that a sea-weed was found in 1856 in China, of which a sample was sent to him for examination. The alga was *Gelidium corneum*, or what is known as agar-agar, and he gives a short account of the properties of colloidal solution obtained by boiling it with water; also he gives an analysis of the substance. He also speaks of it as being the sea-weed out of which gulls build their nests, and that it is the substance which is used by the Chinese in making "birds' nest soup."

In 1862, Stanford ("Jour. Soc. Arts," 10, 186) refers to the peculiar principle in gelose described by Payen, and states that very few algae contain this principle, certainly none to the extent of agar-agar.

In 1874, Heilmann wrote in "Dippels Polytechnisches Journal," but we have not been able to find his paper.

In 1880, Morin ("Comptes Rendus," 90, 924) gives results of a further study of the substance, but these will be included in our work when discussing the properties.

A little later in the same year Porumbaru ("Comptes Rendus," 90, 1,081) communicated the results of his more detailed examination. He gives a more correct analysis of the colloid, but as his own substance contained 3.5 per cent. of ash, it must have been very impure. He mentions that when heated to 150 deg. to 160 deg. C. in sealed tubes, it yields a black humic substance, insoluble in water.

In 1882 Garnish ("Arch. Pharm." [3], 20, 241) gives notes on a carbohydrate obtained from *Fucus amylaceus*, which he compares with Payen's "gelose," this being convertible into arabinose. In this he seems to be in error, as Bauer has shown ("Jour. Prakt. Chem." [2], 30, 375) that gelose yields galactose. He says that gelose is not identical with lichenin.

In 1882, Stanford ("Jour. Soc. Chem. Ind.," 3, 297), in discussing algin, speaks of *Gelidium corneum* and gives the different amounts of four substances required to form jellies of equal consistency; he also gives the "melting points," but these are the solidifying points and not the melting points:—

Substance.	Parts required.	Setting point.
Gelose .....	1 .....	90° F.=32° C.
Isinglass .....	4 .....	70° F.=21° C.
Gelatine .....	8 .....	60° F.=15.5° C.
Carrageenin .....	9 .....	70° F.=21° C.

In 1889, Voigtlander ("Zeit. Phys. Chem.," 3, 316) shows that diffusion takes place in agar, as in water.

In 1902, Desmoulier ("Ann. Chem. anal.," 7, 201) distin-

guishes between gelatine and gelose, by the fact that gelatine gives a precipitate with tannin, picric acid, or lime; but as matter of fact, agar also gives a precipitate with tannin. To separate gelatine and agar, he evaporates to dryness with formalin, and extracts the residue with water. The gelatine is rendered insoluble, whereas the gelose is dissolved and will set.

Py ("Jour. Pharm." [6], 2, 488) suggests the presence of diatoms as being a distinguishing characteristic of gelose in jams.

Levites in 1903 ("Jour. Russ. Phys. Chem. Soc.," 35, 253) shows that in agar solution, chlorides, bromides or cyanides accelerate gelatinisation; salts of monobasic acids retard, whilst salts of polybasic acids accelerate gelatinisation.

Before considering the reactions in detail, it will be necessary to refer to certain matters, as I am legally compelled to do so, and also they are very instructive. Last year, I was approached by Mr. P. Gillard, and asked to take up a new paper which he claimed to be his own invention. Demanding that he should demonstrate his process to me, I gave him facilities to do so in my laboratory. The paper was to be a self-toning paper in agar containing gold and platinum, and having certain properties. Some of these papers were undoubtedly good, but one could not be certain of the result of any particular coating. Mr. Gillard failed very materially, in that he could not turn out consistent results. These failures are of great interest, however, and I suppose that the difficulties which prevented him from turning out consistent results, are the same as would be encountered by others trying to use agar. Therefore they will be of interest, and we think we can point out the reasons and how to overcome them. We may mention here that Messrs. Morgan and Kidd are turning out agar P.O.P., and therefore it is possible for others to do so; moreover there are agar papers on the market in Germany. It is quite obvious to us that agar can be used as a medium for plates and bromide paper.

Mr. Gillard's failures were chiefly:—

- 1st. The agar solution was not clear, containing small granules.
- 2nd. In making the emulsions one found that it would become thin and limpid, and would not set.

(This was termed peptonising: but the term is quite wrong, as peptones are nitrogen compounds, whereas agar contains no nitrogen, and therefore cannot be peptonised. We use the term de-gelatinise therefore.) This second fault would occur, sometimes in making the emulsion, sometimes when made and whilst coating; sometimes it went limpid as a whole, while at other times it occurred in parts, causing a peculiar granular appearance.

- 3rd. Agar does not dissolve in water, unless heated to 100 deg. C., i.e., the temperature of boiling water.
- 4th. If cooled to 32 deg. to 35 deg. C. it sets very quickly and then will not dissolve again unless boiled once more; if this be done with an emulsion it is often quite spoilt.
- 5th. When he added his gold chloride to the emulsion, it was necessary to get it on to the machine without a moment's delay, otherwise the gold was reduced to the metallic state before the emulsion was on the paper. The causes of these difficulties, and methods to overcome them, will be explained later.

When I inquired of Mr. Gillard what knowledge he had of agar, I found that practically nothing was known: I could get no books on the subject, so that it was necessary to set to work

look up references to it, and to ascertain its properties. This is the work which Mr. Nuttall and myself have undertaken. The first question is: "What is agar?" "To what class of substance does it belong?" It has been shown by Payen and Porumbeu that it does not contain nitrogen, therefore it is not a proteid, peptone, or albumen; nor yet is it a proteoid or an albumenoid, i.e., it is not a gelatine, nor a glue; it differs very materially from all these in its properties. It seems that it must be placed amongst the more complex carbohydrates, celluloses, starches and gums. On oxidation with nitric acid the two elements yield oxalic acid, whereas the gums and agar-agar yield acetic acid. For this reason Allen classifies it as a gum. Senior so classifies it as a gum. It has been shown by Payen ("Jahresbericht," 1859, 562) to be similar to, or to yield, Pararabin or Stet-sugar gum. From its properties it appears that this is the correct group in which to put it, therefore, though in many of its properties it is anomalous.

As bought, it is in the form of long translucent, stringy pieces, tough, dry, and hard. Soaked in water, it swells up as do gelatine and the gums. The soaked substance dissolves in water when boiled, and then only slowly. Our method of dissolving is to cut up the agar into small pieces; soak them in running water for some hours; then place in distilled water; heat the water until it boils, and continue the boiling for a quarter of an hour, stirring vigorously the whole time. If the boiling is not continued long enough two things will be noted: firstly, that the solution is lumpy, i.e., that the agar has not dissolved completely; and, secondly, that it is more difficult to strain.

For bacteriological purposes the treatment at the Cambridge laboratory is to soak the agar in a 1 per cent. solution of acetic acid for twenty-four hours, wash out the acid in running water, and dissolve up by boiling. We may mention in passing that the acid has no ill effect; we have treated several lots in a similar manner with good results, but the treatment seems to be unnecessary.

Having dissolved the agar, we proceed to strain it, in order to retain solid impurities. This we do in practice through main-cloth (we shall be dissolving some up in a short time, and the process will then be seen). The solution is then fairly clear, but contains a large quantity of peculiar, slightly opaque specks, and is not quite transparent as gelatine is. This renders it useless for use in emulsions for plates, but the solution can be made perfectly clear by filtering. At Cambridge it is filtered through a special paper in a large funnel, the whole being enclosed in a steam-jacketed chamber, which keeps the agar hot. (The paper can be bought from any dealers in chemical apparatus.) We dissolve each gram of air-dried agar in 50 c.c. of water, which makes a 2 per cent. solution. This is then filtered at as high a temperature as possible through a hot Buchner funnel, using a pump, the flask being placed in hot water. Such a solution is quite clear and transparent.

This forms the solution of gelose. Such a solution has the following properties, though in giving these we must note that the age of the sea-weed seems to have some effect on the properties; our results do not quite agree with those of earlier workers.

A solution of agar in water sets when cooled, the temperature at which it sets being about 33-35 deg. It sets very rapidly when cooled to the setting temperature, more rapidly than gelatine. The gelatinising property is very great; it is said to be ten times as great as gelatine. Stanford puts it down as eight times as great; Allen states that gelose will form a jelly with 500 times its own weight of water.

Peculiarly enough, and entirely different from gelatine, a solution of gelose can be boiled for a long time without becoming much less viscous. Indeed, we frequently evaporate a solution which is too weak by boiling until it is quite thick. We may boil some solutions for an hour or more. Any agar which remains over from an experiment is allowed to set, and is kept for some days; when making an emulsion, we boil it up with more

water and evaporate off the excess. We found that after boiling for a quarter of an hour, the agar solution was slightly less viscous, but that continued boiling, within reason, does not make much difference for practical work. The boiling solution must be vigorously stirred in order to prevent it from being burnt; if burnt, it is quite useless for emulsions, as it produces a very dirty colour. This peculiarity is of importance. Gelatine is a nitrogen compound, and when hydrolysed by boiling or by heating with acids or alkalies, it forms various compounds, amongst which are leucine and glycocoll and ammonia. Leucine is ammonia in which one hydrogen atom is replaced by the caproic acid group; it is an amide. Glycocoll is ammonia in which one hydrogen atom is replaced by the acetic group; it also is an amide. These two compounds are such as one would expect to cause for in an emulsion, just as ammonia does, and we think that the spoiling of emulsions in gelatine may be put down to this cause in part. Now agar cannot form such compounds, though it may form aldose compounds which would reduce the silver; certainly if heated with water under pressure, gelose is hydrolysed and yields a sugar. This may account for some of the difference between working in agar and in gelatine.

On soaking agar and squeezing to extract the surplus water, we noticed that some matter appeared to be washed out. We took some agar and soaked in distilled water, poured off the water through a filter paper, and added a further quantity of distilled water. We repeatedly poured off the water in which the agar was soaked, at intervals of about an hour. The washings were then evaporated to dryness, and it was found that 18 per cent. had been washed out of the agar by the water, for the filter paper would have retained any solid matter.

Air-dried agar usually contains about 21 per cent. moisture, driven off at 100 deg. C.

The percentage of ash in our sample was .487 per cent.

The density of a solution of agar at 50 deg. C. is less than that of water at 50 deg. C. We attempted to determine if the density could be used to ascertain the amount of agar in solution, but this has not been done up to the present.

The viscosity of a solution of agar is much greater than that of gelatine with the same percentage of solid. We have estimated that a solution of gelatine of definite strength is about as "thick" as a solution of agar containing  $\frac{1}{8}$ th of the amount per cent., this agreeing with the figures given by Stanford.

Barker's P.O.P. formula contains 8 per cent. of gelatine; Valenta's contains 9.6 per cent.; Beadle's contains 11 per cent., so that a solution of agar 1-1 $\frac{1}{2}$  per cent., or 2 ozs. to the gallon, should be sufficient. We recommend that those trying agar for the first time should start with a 1 $\frac{1}{2}$  per cent. solution.

A solution of 3 per cent. is difficult to use, as it is too thick. We find a 1 per cent. solution is most convenient, though a 2 per cent. solution is quite easily worked. A 1 per cent. solution is about as thick as an 8 per cent. solution of gelatine. If two emulsions containing the same amounts of chemicals, except that the medium in the one is gelatine and in the other is agar, and if the solutions are of the same "thickness," then the amount of agar will be one-eighth the amount of gelatine: in coating a plate or paper with these solutions and drying one will get the same amount of silver per square foot, but only one-eighth of the amount of medium when using agar. In the case of paper this would not matter so much perhaps, but with plates it means that the pellicle will be extremely thin. It will be of great interest to ascertain what influence this has on the sensitiveness of the emulsion and on the development. If the pellicle is so much thinner the light will be able to act more rapidly on the sensitive salt and should give increased rapidity. One would expect that in development, the developer would penetrate more rapidly and therefore develop more energetically; on that account also less exposure should suffice. In that case, one should be able to obtain plates of extreme rapidity, great latitude, and with a fine grain. Would the gradation be as delicate,

however? The plates which we made, worked like wet plates; they were developed and washed as quickly. One of them will be shown to-night which was intensified with mercuric chloride and potassio-silver cyanide three times, and completely washed, all within five minutes: it will be seen that (though the plate is badly coated) there is a total absence of the stain which would have existed had the intermediate washings been incomplete. This emulsion was matured by being plunged in boiling water for five minutes. The speed was about 65 H. and D.

The following do not form a precipitate with the solution of gelose:—

- |                               |                       |
|-------------------------------|-----------------------|
| 1. Copper sulphate.           | 9. Platinum chloride. |
| 2. Lead acetate (normal).     | 10. Gold chloride.    |
| 3. Nickel sulphate.           | 11. Chlorine.         |
| 4. Mercuric chloride.         | 12. Bromine water.    |
| 5. Iron chloride.             | 13. Iodine.           |
| 6. Iron sulphate.             | 14. Chromic acid.     |
| 7. Potassium bichromate.      | 15. Picric acid.      |
| 8. Potassium chloroplatinite. | 16. Formalin.         |

The following give a precipitate with the solution of gelose:—

- |                     |                        |
|---------------------|------------------------|
| Basic lead acetate. | Phospho-tungstic acid. |
| Mercuric nitrate.   | Alcohol.               |
| Tannin.             |                        |

The reactions with many reagents are tabulated below, and from it can be learnt the chief differences between agar and other compounds.

Though the presence of small quantities of mineral acids the solution causes it to lose the gelatinising property, yet the solid substance soaked in water can be treated in the cold with dilute acids and alkalis without doing much harm. Hydrochloric and sulphuric acids, however, dissolve the agar: Payen says that it is dissolved by the concentrated acids, to form a hard brown mass which is insoluble in almost any ordinary reagent. We have found that it forms a brown solution, but we have not obtained the hard, insoluble mass. The solid agar can be boiled with glacial acetic acid without much change; but containing water it dissolves the agar on heating. The 1 per cent. solution used for soaking, will have no detrimental effect but will keep in solution all iron salts contained in the water and so tend to prevent discolorations. Agar soaked in 10 per cent. acetic acid, however, then washed, and dissolved, had lost considerably in viscosity.

The effect of alkalis on agar is to make the solution lose its setting properties, but at the same time it makes it a little more sticky and gummy. With a fresh solution of agar, if one puts one's finger into it the adherent drop soon separates from the main part of the solution; but when heated with a small quantity of alkali, the solution becomes somewhat more sticky and the drop does not immediately separate from the main part of the solution.

On adding borax to a solution this effect is greatly augmented.

THE CHIEF REACTIONS ARE SHOWN IN THE FOLLOWING TABLE:

Reagent.	Agar.	A line indicates no reaction.			
		Gelatine.	Proteids.	Peptones.	Albumen.
Millon's	—	pp. red on boiling.....	pp. red on boiling.....	pp. red on boiling ...	?
Biuret	—	—	Violet	Red, free from violet	Violet.
Adam Kiewitz (HA + H <sub>2</sub> SO <sub>4</sub> ) ...	Brown.....	Slight pink .....	—	Reddish brown .....	Pink.
Tannin	pp. ....	pp. ....	pp. ....	pp. ....	pp. ....
Xanthoproteic (HNO <sub>3</sub> ) .....	—	Given	Given	Given.....	pp. ....

Iodine .....	Colour red	Colour yellow brown	—	—	—

Alcohol will precipitate a solution of gelose, if added in sufficient quantity. A solution containing 1½ per cent. of the solid dried at 100 deg. C. (about 2 per cent. ordinary dry agar), is precipitated by adding about 40 per cent. of rectified alcohol; whereas it appears that, to a solution containing 2½ per cent. of the solid dried at 100 deg. C., even more than 40 per cent. may be added without definite precipitation. If a solution of agar be poured into excess of 90 per cent. alcohol a white precipitate is formed at once, which collects into a coagulum, which can be separated by muslin or filtered paper. Payen states that precipitation of agar by alcohol is not a good method, as it increases the percentage of ash, or solid matter. In our experiment, the ash before precipitating was .487 per cent., but after precipitation by alcohol it was 4.06 per cent.; though we think this is somewhat excessive. Certainly part of the agar is left in solution in the alcohol, because, on evaporating the alcoholic filtrate to dryness, a gummy mass was obtained. Is this part of much importance to the photographer? At present, we cannot say.

Like gelatine, when heated with acids or alkalis, the setting property is destroyed.

and the solution becomes so sticky (tacky) that one can draw out strings of the substance some feet in length. On rubbing between the finger and thumb it will be noticed that the untreated solution has more "body," but is much less "tacky." We are of the opinion that this property will be found of great use in the practical application. We have coated paper with such a solution quite readily. The solution treated with borax in this manner sets, though much more slowly than when not so treated. The resulting jelly is much less friable and seems to be more tenacious.

The reaction with iodine is peculiar. On adding iodine, either in potassium iodide or in alcohol, to a hot solution of gelose in water, the light yellow colour, due to the iodine, remains. On cooling, however, the yellow changes to a red purple, very much like that of iodine vapour. On heating, the purple changes to a yellow once more: the purple is developed again on cooling, and one can cool and warm repeatedly, with the same effects. There is not a perfectly sharp temperature at which this takes place, but it is between 27 deg. C. and 29 deg. C. This darkening and lightening can be detected when so dilute as 1 part in

10,000. On adding hydrogen peroxide to the mixture of gelose and iodine and warming, the red purple given when the solution is cooled changes to a blue similar to that given by iodine and starch. This disappears on warming, and reappears on cooling: but it is quite transient, and the exact conditions determining this blue colour, and its cause and meaning, have not yet been ascertained.

Agar will absorb a small quantity of iodine, and also of bromine, the amount being 1.65 per cent.; whereas gelatine absorbs 6.21 per cent., at 15 deg. C. This difference will be of interest in considering any theory of the latent image in agar as compared with that in gelatine. We may say that though one would suppose, on theoretical grounds, that on this account agar would be less suitable for emulsion work than gelatine. But it is not so. We find that its physical properties are not inferior to that of gelatine, and with scarcely any maturing one can prepare a comparatively fast emulsion. We shall show some lantern slides, made on plates with a speed of about 65 H. and D. Earlier it has been mentioned that a pellicle of agar will be about one-eighth as thick as a similar one of gelatine; so that the comparative ability to absorb iodine will be 6.2 per cent. for gelatine, and  $1.65 \div 8 = 0.2$  per cent. for agar: that is to say that, per area, gelatine will absorb about thirty-one times as much iodine as will agar.

Silver nitrate forms no precipitate with a solution of gelose, but on mixing a hot solution and keeping hot, darkening in colour takes place: this also occurs slowly at 50 deg. C., different samples varying considerably in the time necessary for the darkening to take place. But in any case, even boiling, it is not less than ten to twenty minutes, and may be quite a long time, so that one has sufficient time for making an emulsion. If a small quantity of hydrogen peroxide be added, no discoloration takes place at 50 deg.; but whether this is due to the oxidation of any aldehyde formed, to the acid, we cannot say at present. Citric acid also acts as a preventive of discoloration, but not so much so as hydrogen peroxide.

Silver-ammonio-nitrate gives no reduction at 50 deg., only on boiling. The solution of agar which has been boiled for some time gives but little more reduction than that which has been freshly made.

We find that our sample of agar does not form a peculiar compound with silver nitrate, similar to that produced with gelatine.

Fehling's solution is not reduced by a fresh solution of agar; but by boiling with acids (such as sulphuric acid) the gelose is hydrolysed to form a sugar which reduces Fehling's, and which gives a precipitate with phenyl hydrazine. This is being further studied, and the sugar is being identified.

The distillate of a solution of agar boiled with dilute sulphuric acid gives only a very slight colour with aniline acetate, so that no furfuraldehyde is formed, and there is no pentose group existing as such in the agar. It forms a very slight precipitate with phenyl hydrazine. The further study of these sugars and the products of hydrolysis are not of sufficient interest to the photographer to include here, but will be dealt with later. See Bauer ("J. Prakt. Chem." 30, 367) and Muntz ("Bull. Soc. Chem." 37, 409). It may be that agar is a glucoside, somewhat similar in constitution to fucose, a product also obtained from some varieties of sea-weed. Glucosides on boiling with dilute acids give one of the sugars as a product of hydrolysis.

Sodium meta-phosphate forms a gelatinous precipitate with a solution of agar, on boiling: gelatine gives no such precipitate.

Tannin gives a precipitate with a solution of gelose when it is strong, but it dissolves on heating: the precipitate formed by tannin and gelatine is given in very dilute solution and does not dissolve on boiling in the presence of excess of tannin.

Chromic acid seems to have no effect on agar, such as it has on gelatine: it does not form a precipitate nor does it render it insoluble in water as it does with gelatine. Similarly potassium bichromate does not make it insoluble: neither does alum nor

formalin. A mixture of agar and gelatine can be separated by adding formalin, evaporating to dryness, and extracting with hot water: the gelatine is insoluble, whereas the agar is dissolved. After being rendered insoluble in water, the gelatine may be dissolved in dilute acids and precipitated with tannin.

Gold chloride does not give a precipitate with agar or gelatine soluble; but platinum chloride gives a precipitate with gelatine, and not with agar.

It will be seen, therefore, that the difference between agar and gelatine is very marked. Agar gives no reactions with the colour tests for nitrogenous products; especially it gives no precipitate with picric acid, mercuric chloride, platinum chloride, chromic acid. Its reaction with iodine is distinctive, also that with hardening reagents.

### Curves

We have mentioned that many substances have a peculiar influence on agar in solution; it was also obvious that some chemicals had a greater effect than others; and we sought some method of ascertaining exactly what effect each of those we use would have on the solution. We considered that we should achieve our object by ascertaining the viscosity of the mixtures at varying intervals, since it is a property of great importance to the practical emulsion maker; so we adopted the method and apparatus of Ostwald. This is the one most used for such purposes, both in physical work and in technical determinations of such substances as gelatine, glues, etc., and we had every reason to suppose that it was the best instrument to use for our purpose.

We found, however, that there were several objections and difficulties. The solution of agar contains minute solid impurities, and we found that they were precipitated, and, by blocking the capillary, caused serious errors in the rates of flow. It is extremely difficult to be certain of the strength of the solution of gelose owing to the fact that, to get it into solution, the water must be boiled and kept boiling for some time, so that a considerable amount of water is evaporated off. At first we thought that it was necessary to use a 3 per cent. solution, which is very viscous, too much so for the experiments and the emulsion making: we adopted this strength because we did not know what viscosity the actual maker obtained with his gelatine emulsions. Mr. Gillard used a 3 per cent. solution of agar, and we concluded that this must be the best strength, so that we persevered with a 3 per cent. solution for a considerable time. Great care has to be taken not to get any part of the apparatus cooled when manipulating the agar, and adding the chemicals. These and other practical difficulties have shown us that the method is not well adapted to the object in view—at least, not without several modifications.

We have our results, and though we must admit that owing to the practical difficulties they are inaccurate, yet they are sufficiently accurate to be of interest, inasmuch as they give a fair estimate of the relative effect of the chemicals; as these relative effects are of extreme importance practically, we consider that it is worth while showing them. The whole, however, is being undertaken afresh, with a modified and different apparatus, using perfectly clear agar of a 1 per cent. concentration.

The viscometers used by us, are made with a wider capillary than usual, and standardised with phosphoric acid sp. gr. 1.5. In the most convenient ones, the time taken to run from the upper to the lower mark was about 60 seconds at 15 deg., or 24 seconds at 50 deg., that used for such chemicals as nitric acid took 383 seconds at 15 deg., and 113 seconds at 50 deg. In all experiments 3 grams of air-dried agar were dissolved in water, and made up to a final weight of 103 grams. We consider that this is much too concentrated, and that a 1 per cent. solution would be better.

The agar was soaked in running water overnight, dissolved in distilled water by boiling, boiled for a quarter of an hour, made up to the correct weight, strained, cooled to 50 deg. C., then

mixed with solutions of the chemicals heated to 50 deg. C., immediately placed in the viscometer and a reading taken.

Fig. 1.—These curves show the degelatinisation, at varying intervals of time: we must repeat that they are not accurate owing to the difficulties of the work; but they illustrate the effects produced in actual work and so are instructive.

In the case of nitric acid, decinormal, it is seen that in ten minutes the solution is only 72 per cent. as viscous: after twenty minutes it is 64 per cent.: in sixty minutes it is 11 per cent. as viscous: if left longer it becomes only 8 per cent. as "thick" as at the commencement.

Tartaric acid, decinormal, causes the solution to become only

has not been determined, as the capillary of the viscometer became blocked up.

Fig. 2.—The next set of curves, taken more exactly, show the comparative effect of citric, tartaric, and nitric acids. The results are very similar to those shown in the previous diagram. Nitric acid has a great degelatinising power; tartaric acid is almost as potent. The effect of citric acid is very much less than that of either of the other two, and is never very great.

The practical application of these results can now be seen. In preparing emulsions such chemicals as free tartaric or nitric acid should be avoided; similarly, combinations of chemicals which react to produce free nitric or tartaric acid cause dege-

The curves, reading from top to bottom, are for N sodium chloride, N ammonium chloride, N/10 citric acid, N/10 tartaric acid, N/10 nitric acid, and N/10 acetic acid.

Fig. 1.

about 69 per cent. as thick, in twenty minutes: in time (about two hours) it will be 23 per cent. as viscous.

The curve for acetic acid, normal, is very erratic: probably the capillary became somewhat choked after sixty minutes. But it certainly has a considerable effect.

Citric acid, decinormal, has a small degelatinising effect, and even after one hour it reduces the viscosity to no more than 80 per cent.

The effect of silver nitrate, normal, is marked at first but after ten minutes there is not much alteration. The manner in which

The curves are those for N/10 citric acid, N/10 tartaric acid, and N/10 nitric acid.

Fig. 2.

the line rises after a lapse of time is curious. The same peculiarity occurs in the curve for sodium hydrate.

Sodium hydrate, normal, has a very considerable degelatinising power.

Sodium chloride has no effect whatever. Ammonium chloride, however, makes it more viscous, and in thirty-two minutes the solution has become 8 per cent. "thicker." It gradually becomes less viscous, and in about eighty minutes it returns to its initial viscosity.

The effect of borax has been mentioned already. The curve

latination. In such a reaction as that between silver nitrate and iodine in solution, wherever a grain of silver iodide is formed, there is a concentration of nitric acid round it; this causes local degelatinisation; hence the granular appearance of some of Mr. Gillard's emulsions; also it would cause coagulation of the silver haloid by destroying the colloidal nature of the medium. We found, in making emulsions, that this coagulation was a common accident, and we ascribe it to this cause. It should be mentioned that Rochelle salt, which Mr. Gillard

Fig. 3A.

Fig. 3B.

frequently used, has an effect similar to tartaric acid in its power of degelatinisation.

Mr. Gillard, in mixing some of his chemicals with the solution of gelose, did not dissolve them, but added them solid. This would cause excessive local concentration, and must have been responsible for the peculiar "boiled rice" effect in his emulsions. We have repeatedly made emulsions to his formulae, quite successfully, but we dissolved the chemicals in water and added them gradually.

An acid is required in a P.O.P. emulsion to make the paper keep, and preserve the whites. It will be seen from the curves that, of those examined, citric acid has less degelatinising effects than others, and should be best adapted to that purpose. We have made many emulsions with it, and have found it quite suitable.

We are now in a position to discuss the failures of Mr. Gillard, mentioned previously, and to see how to avoid them.

1. The opacity was due to incorrect manipulation, and can be overcome by filtering the solution of gelose at a strength of about one and a half per cent.

2. The degelatinisation is due to the presence of certain chemicals in the emulsion, either added or formed by the reactions in emulsifying. The value of the curves will now be apparent. It has been shown that nitric acid, even in small quantities, has a very great degelatinising effect: that tartaric and acetic acids are also detrimental: that citric acid does affect the viscosity, but not to any material degree. Therefore, it is advisable to use citric acid in preference to others in order to make the paper keep.

It should be noted that if tartaric acid is required in an emulsion, then the emulsion should be made very much thicker at first, so that the tartaric acid may reduce the viscosity to the required degree.

3. The difficulty of solution causes no trouble except in washing emulsions. We are told that we cannot dissolve the emulsion after it has been set and washed; but we show a sample of bromide paper of about the same speed as "Nikko," also some lantern-slides, all made with emulsion which has been washed and set, then dissolved. There was scarcely any fog at all in these during development.

4. The setting of the emulsion is due to careless manipulation. In pouring from one vessel to another, the second vessel must be heated to about 40 deg. C. In coating, also, the same point must be noted.

The reduction of the gold chloride was due to using the salt which reduces the gold most easily. In P.O.P. emulsions there is excess of silver nitrate over the amount necessary to form the silver haloid, and this makes the reduction take place more easily. The notes on the reducibility of gold chloride should be of use here.

#### Apparatus for Drying Agar-Coated Paper.

Since agar, when once set, is insoluble in water unless heated to boiling, it seemed to us that the paper off the coating machine could be dried very quickly by means of hot air. An experimental apparatus was made on a small scale. A long tubular wooden tube of rectangular section was made (see Fig. 3). The total length was 55 feet; it was about 10 inches wide and about 3½ inches deep. Paper 8 inches wide was drawn through it. This paper was supported in the tube by glass rollers (made from glass tube) placed about one foot apart. The end into which the paper entered was open; the other end was closed by two pieces of wood covered with plush, pressed together. About 8 feet from the exit end a box was placed under the tube, and com-

munication was made between the box and the bottom of the tube by means of holes bored through. At the same time communication was made with the box and the top of the tube by means of glass tubes as shown in Fig. 3b. A large iron pipe leading from a blacksmith's bellows through a furnace opened into the box below the tube.

The iron pipe was heated to redness, and air was blown through it by means of the bellows. The wooden tube having been made air-tight, the only exit for the air was at the open end where the paper entered.

The solution was then put in the pan and the paper coated and drawn through the wooden tube as shown in Fig. 3 A and B. After running for a short time the paper on the receiving roll was quite dry, and by tearing open the box at a distance of 36 feet from the paper inlet-end it was seen that the paper was perfectly dry there; it may have been dry before it reached that point, but we could not ascertain this, as the tube was nailed up. The speed at which the paper was being drawn through this was ascertained by taking the time for a mark to run through the tube, and was found to be 4 feet per minute. A wooden shuttle 3 feet long was used to pull the commencement of the paper through the tube and to lead it over the rollers. Two strips of tape drawn through the apparatus under the paper served to support it and prevent it from breaking. Baffle plates were inserted in the tube to mix the air, and to keep it on to the upper and lower surfaces of the paper.

It will be noted that the hottest air met the driest part of the paper, so as to complete the desiccation, and that the paper was dried from both sides.

Rate of paper	...	...	...	4 feet per min.
Time taken to dry	...	...	...	11.5 per min.
Highest temperature	...	...	...	84° C. = 183° F.
Lowest	"	...	...	43° C. = 109° F.
Distance at which the paper was dried	...	...	...	36 feet.

From these figures it will be seen that the agar-coated paper can be dried quite readily in a short time.

In conclusion, it is hoped that though our work is necessarily incomplete, yet enough has been done both to form the basis of future study and also to assist the practical user in the chief of his difficulties. Agar-agar has certain advantages over gelatine, and we firmly believe that its use will be much more common in the future. Its cheapness is no inconsiderable item, the cost being less than gelatine, and only about one-eighth the amount being used. Its insolubility in water under a temperature of 80 deg.-90 deg. C. enables very hot water to be used in washing; at the same time, prints can be dried with extreme rapidity over a naked flame. Certain chemicals can be used in agar which cannot be added to gelatine, such as platinum chloride. The pellicle of agar is very much thinner than that of gelatine—about one-eighth the thickness—so that toning, washing, and other manipulations can be carried out much more quickly.

W. F. COOPER, B.A., F.C.S.

W. H. NUTTALL, F.I.C., F.C.S.

A MOTOR SKIRT and other wearing apparel was alleged to have been stolen from the house of Mr. John Hardy, photographer, of 190, Witham Road, Sheffield, by a domestic servant. The case came before the Sheffield magistrates last week.

**THEFT OF LENSES.**—At the Liverpool Sessions, last week, William Bernard, photographer, of 67, Railway Street, Southport, was sent to gaol for six months with hard labour for stealing two photographic lenses from the shop of Mr. T. J. Gidden. The evidence showed that the prisoner had been employed on various occasions by Mr. Gidden, and that some time afterwards he offered two lenses to Bernard McClusky, of Fisher Road, Birkdale, for £5. McClusky bought the

lenses for £2 2s., but afterwards gave information to the police. His suspicions, he told the Bench, became aroused when the prisoner asked him to buy other articles.

**LONGTON AND DISTRICT PHOTOGRAPHIC SOCIETY.**—The annual exhibition will be held from February 19 to 21, the closing date for entries being February 8. There will be five open classes, including one for colour photography, prints, or transparencies by any process. The awards will take the form of vases and other artistic and useful pottery productions. Mr. C. F. Inston, of Liverpool, will act as judge. Entry forms, which are now ready, may be obtained from Mr. T. Mottershead, 32, Stafford Street, Longton, Staffs.

## THE PYRO-SODA DEVELOPER.

[A paper read before the Société Havraise de Photographie.]

PYROGALLIC acid is one of the oldest developers, and has therefore suffered much at the hands of the formula makers. The many formulæ for its use, however, may be divided into two classes: 1, Pyro-ammonia; and 2, pyro-soda. Pyro-ammonia is, I think, that which gives the most brilliant and the better results, but it demands some skill, and, moreover, has the disadvantage of giving a peculiar dichroic fog, red or green, in those parts of very rapid plates which have not been sufficiently exposed to light. Personally I do not consider this a disadvantage in the strict sense of the word, but at the present time a perfectly clean negative is required, and pyro-ammonia does not always give this.

Pyro-soda, on the other hand, gives beautiful negatives, and it is of this alone that I intend to speak. I do not propose to consider all the formulæ that have been given, but to describe my method of working, and I can assure anyone who will exactly follow my advice that he will obtain perfect results.

Before all things it is essential that the chemicals used must be absolutely pure. I have given up the use of dry pyro measured out as required with a mustard-spoon in favour of a solution of definite strength. Pyro, when quite pure, is a perfectly white substance, very liable to alter on exposure to air. To keep it, it is essential to preserve it from contact with the air, even in a dark room.

I keep the following solution ready for use:—

### Solution A.—Pyro.

Pyro .....	5 gms.
Nitric acid .....	5 drops.
Boiled water .....	100 ccs.

The water is first boiled to expel the air which it always holds in solution. When it has cooled down 100 ccs. are measured out and 5 drops of pure nitric acid added, and then the pyro, which must be quite pure and white. Solution takes place instantly. If the mixture contains any particles of dirt I filter it through a compact plug of absorbent cotton wool, never through filter paper. Under these conditions the solution will keep white for several weeks. The stock of pyro in powder must be kept in a well-corked bottle, and it is advisable to cover the cork with paraffin wax; 5 ccs. of the stock solution contains exactly 0.25 g. of pyro.

### Solution B.—Carbonate.

Sodium carbonate crystal .....	20 gms.
Sodium sulphite crystal .....	20 gms.
Water, to make .....	100 ccs.

The carbonate of soda is merely the ordinary carbonate, known as soda crystals. The sulphite, on the other hand, ought to be as pure as possible and ought to contain neither sulphate nor carbonate. The method of purifying the sulphite, or at least of eliminating the carbonate, is as follows: it is sufficient to add a little acid sodium bisulphite lye, which in contact with carbonate forms sulphite of soda. In order to determine the quantity to add test paper of phenol-

phthalein may be used. This can be obtained commercially, but can be very easily prepared as follows:—

Solution phenolphthalein (comm.).....	1 part.
Water .....	5 parts.
Alcohol .....	5 parts.

White blotting paper should be immersed in this and dried. This test paper, which is quite white, turns a bright red in contact with alkalis and alkaline carbonates, and remains white with pure sulphite. Thus in order to confirm the purity of a solution of sulphite it is only necessary to wet a slip of the phenolphthalein paper; if it remains white the sulphite is free from carbonate. This, however, is rarely the case, and it usually turns red, proving the presence of carbonate of soda. The bisulphite lye should then be added till the paper does not turn red. A solution of sulphite will thus be obtained free from carbonate. To prepare Solution B, dissolve the sulphite in 50 ccs. of warm water and neutralise with bisulphite lye until the solution no longer reddens phenolphthalein paper. Add the carbonate and allow to dissolve, and then add sufficient water to make the total volume, when cold, 100 ccs.

Five ccs. of this solution will contain exactly 1 gm. of sodium carbonate and 1 gm. of sulphite. The result will be that every time one adds carbonate to the developer one also, adds an equal quantity of sulphite. This is very important from a practical point of view, for the more alkaline the developer the greater the tendency to oxidise and to stain. There is then a distinct advantage in increasing the sulphite, that is the preservative, in the same ratio as the carbonate is increased.

### Solution C.—Bromide.

Potassium bromide .....	10 gms.
Water to make .....	100 ccs.

These solutions having been made, here is my method of working. Whether I have to deal with an instantaneous or time-exposure I always treat the plate with a developer of constant composition as regards the pyro and carbonate, thus:—

Water .....	100 ccs.
Bromide solution C <sup>1</sup> .....	2-5 drops.
Pyro solution A .....	5 ccs.
Soda solution B .....	5 ccs.

This formula represents, I think, the "normal developer" for a plate which has received normal exposure. I pour this solution over the plate and watch the appearance of the image. According to the manner in which this takes place, I then determine—and not until then, what I have to do to obtain perfect development. According to the plate used, the temperature, etc., the image may appear with greater or less speed. Whatever may happen, I always wait until the image has appeared before modifying the composition of the bath. Here my advice must cease. What is to be done can only be acquired by practice. If the development is slow it is a sign of under-exposure. In this case add more carbonate, little by little, or 2 ccs. at a time. If development proceeds in a normal manner, allow the developer to act, and towards the end add carbonate, 1 cc. at a time, to give density. If the image appears very quickly it is a sign of over-exposure, add then 5 ccs. of pyro, or more if necessary.

H. REEB.

<sup>1</sup> The bromide is not absolutely essential: I do not use it for instantaneous work. It delays the appearance of the image and the general progress of development.

### A NOTE ON THE BACKGROUND.

THOUGH a background may be a troublesome and sometimes a dangerous companion to the figure subject, it is, nevertheless, capable of being made a most valuable ally; for though in general it should be negative and retiring in order to give due prominence and force to the subject, it often affords the photographer an opportunity of showing his originality by the introduction of striking transactions or ingenious allusions, as do many of the backgrounds of Teniers, Jan Steen, Ostade, and others of the Dutch and Flemish schools of painting. Writing on this subject in the "Journal of the Photographic Society of Philadelphia," Dr. John Bartlett says: "Besides, the background may be of great technical service in giving vigour to parts of the portrait subject by relieving the figure against it, or

softness and repose by losing in it unsightly but necessary features of the subject.

"The Italian painters of the fifteenth century, especially the Venetian school, sought to relieve their figures when dressed in dark clothing by backgrounds lighter in tone, thus giving them a distinct and, at the same, a natural appearance, the gradations in the background tones enveloping the figures in an atmosphere which made them stand out in relief.

"Reynolds considered the strong relief as less desirable than breadth and fullness of effect, and hence his figures supported the strong shadows by still stronger darks of the background. In consequence of this method, he frequently altered the relative tone of the picture, making a black coat, for instance, assume the appearance

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents have been received between January 6 to 11:—

**CAMERAS.**—No. 338. Improvements in folding cameras. Arthur Lewis Adams, 24, Charing Cross Road, London.

**CINEMATOGRAPHY.**—No. 453. Improvements in and relating to cinematography in natural colours. William Norman Lascelles Davidson, 37, Chancery Lane, London.

**PHOTO-TELEGRAPHY.**—No. 464. Improved apparatus for wireless or transmission by wires of photographs and the like. Ferdinand Von Madaler, 61, Stanley Street, Battersea, London.

**ENLARGING.**—No. 471. Combined contact-printing and enlarging machine, specially suitable for use with bromide paper. Henry Spencer Hicken and Leopold Baun, 30, Queen Street, Portsmouth.

**CINEMATOPHONES.**—No. 562. Apparatus for moistening cinematographic bands or films. Eugène Louis Amédée Lertourné, Birkbeck Bank Chambers, Southampton Buildings, London.

**SHUTTERS.**—No. 563. Improvements in shutters for cinematographs. Eugène Louis Amédée Lertourné, Birkbeck Bank Chambers, Southampton Buildings, London.

**CAMERAS.**—No. 599. Improvements in photographic cameras and surveying instruments. Philip Waterhouse, 6, Bank Street, Manchester.

**PHOTO-TELEGRAPHY.**—No. 658. Improvements in and relating to pictorial telegraphy. The Amalgamated Radio-Telegraph Company, Limited, 7, Southampton Buildings, London.

**PLATE-HOLDERS.**—No. 723. Improvements in plate-holders. George Brown Hall, 53, Chancery Lane, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**AGAR-AGAR PRINT-OUT PAPERS.**—No. 2,156, 1907. By the invention, the cost of the production of a photographic silver or other printing-out paper is very considerably reduced, and the trouble which is experienced by makers due to the varying qualities of the highly-finished baryta surface papers which they obtain for the manufacture of printing-out papers is likewise avoided. Moreover, more varied products may be obtained.

In carrying this invention into effect according to one manner, use is made of a plain paper, in the manufacture of which a sizing of a resinous nature has been employed. This paper is not provided with a baryta or other highly-finished coating. The sizing used in the paper may be ordinary neutral resin size or an acid resin size, such, for example, as the free resin sizing suggested by C. Beadle or Wurster. Upon this resin-sized non-coated paper is spread a liquid solution of agar-agar carrying the sensitive chemicals.

In some cases it is advisable to add borax or alcohol, or both combined. The effect of borax on the solution is peculiar, producing a tackiness or stickiness and a peculiar consistency which is of advantage in the operation of sizing or coating. Alcohol has the effect of causing the emulsion to spread better and to decrease the so-called "grease spots."

An important feature found with emulsions in agar-agar is that they set practically directly they are placed upon the paper. The rapidity of the setting may, however, be increased artificially, if desired, by lowering the temperature of the large setting roller, over which the paper is passed in the usual manner.

A further important feature is that the emulsions in agar-agar coated upon a resin-sized paper may be dried much more rapidly than can emulsions in other carrying media coated upon such papers as are at present generally in use. This is due mainly to two causes: Firstly, because a much higher drying temperature can be safely used with emulsions in agar-agar than with gelatine emulsions; secondly, because there is no baryta or other such impermeable layer between the emulsion and the paper.

These two important features of rapid setting and quick drying prevent the emulsions from sinking into the papers before it is dried so that they cannot affect the papers nor be affected by them because the emulsions are set and dried before they can get into the papers.

It is known that chemicals in a set colloid such as gelatine or agar-agar react chemically as if in true solution so long as it is in the "set" condition—i.e., contains moisture; when these colloids are dried the action ceases or is very much diminished. In ordinary work with baryta-coated papers it takes from three to four hours for the emulsion to dry, so that there is time for the chemicals to "wander" into the body of the paper and react with it. But, according to the above process, the drying takes only about half an hour or even less. A good surface is obtained and the printing-out paper produced possesses excellent and enhanced keeping qualities. No claim is made herein for the use, *per se*, of agar-agar as a sensitive medium or vehicle, nor for employment of a paper coated with a solution of resin or resinous gum for carrying a sensitive emulsion, but the two specific claims are:—

1. Manufacturing photographic paper by applying emulsions in agar-agar to non-coated papers sized with a resinous material, as described.

2. A photographic printing-out paper consisting of a non-coated paper sized with a resinous material and carrying an emulsion in agar-agar, as described. William Francis Cooper, The Cooper Research Laboratory, Watford.

**NON-SLIP TRIPOD SHOE.**—No. 1,787, 1907. The invention consists of a rubber shoe, A. The body part consists of a rubber tube of sufficient thickness to allow of its being easily stretched to fit tightly on the square or other shaped leg, B, or metal shoe without breaking. The open end is preferably formed with a rolled lip, *a*. The other or closed end is made of solid rubber, *a'*, preferably cone-shaped inside to receive the spike, *b*, at the end of the leg, and outside cigar or torpedo shape, and may be ribbed or serrated on the outside at C.

In use the shoe is merely pushed on to the end of the tripod leg, B (the roll, *a*, facilitating the operation), where it fits to the shape of the wood and metal work. When done with it may be

Fig. 1.

Fig. 2.

left in position or removed, at the will of the operator. The roll lip, *a*, again proves of service, as instead of the operator pulling at the end, and so running the risk of tearing the rubber when it is a tight fit, he merely rolls it back upon itself. Alfred William Stainton Sanderson, Mossburn Buildings, Altrincham.

**LANTERN-SLIDE STORAGE-BOX.**—No. 6,794, 1907. The object of the invention is to construct a lantern-slide storage-box in such a manner that when open it forms a holder for the slides both before and after displaying. A rectangular box of suitable dimensions to take the ordinary lantern slides, and of any convenient length, is divided in the direction of its length into two equal parts. The lower part might conveniently be called the storage-box, whilst the upper part represents the lid, which is secured to the storage-box by means of dowel pins. Both parts are similarly partitioned off to form compartments, and the lid, when taken off and inverted, forms a convenient receptacle to receive the slides as they are removed from the lantern.

When all the slides have been changed, it only remains to invert the storage-box and place it on the lid, turn the whole lot over, and the slides will be in their original order and ready for the next display.

In addition to the greater safety and convenience of the foregoing method, a distinct advantage is obtained by the slides projecting well above the storage-box when the lid is removed, thereby enabling them to be readily handled.

The interior surfaces of box on which the slides rest may be

Fig. 1.

provided with felt pads to absorb any shock the box may be subjected to. The invention is applicable to grooved boxes.

Fig. 1 is a perspective view of the changing and storage-box, with the lid taken off and inverted. Fig 2 is a side view showing the manner of closing the box after the slides are changed.

The box, *a*, with its lid, *d*, is divided into compartments, *e*, by the partitions, *f*. After the slides are changed from the box, *a*,

Fig. 2.

they are returned to the compartments, *e*, in the lid, *d*, as shown at *e*<sup>1</sup>.

When the whole of the slides are changed the lower part, *a*, is inverted and replaced, as shown in Fig. 2. The box is then turned over, bringing the lid uppermost, when the slides will be in the correct order for the next display. A carrying strap is shown at *c*, Figs. 1 and 2. Herbert Holmes, Tudor Works, Tudor Road, Hackney, and Houghtons Limited, 88 and 89, High Holborn, London, W.C.

**PHOTOGRAPHIC EMULSION.**—French patent No. 380,188, 1907. The invention consists in emulsions for pigment papers prepared from caseins, globulins, or acid albumins or alkali albumins, sensitised with ferric, ceric, or uranic salts, in addition to the pigment. They are stated to be far more stable when sensitised than the chromated gelatin or gum emulsions, and quite as rapid. After exposure behind a negative, the paper is developed by means of a solvent for the albuminoid—*e.g.*, ammonia, alkali, carbonate, or potassium oxalate solution. J. T. Gateau.

MR. HERBERT HOLT, of the Birmingham Photographic Company, Ltd., wishes to correct in advance any impression that he is the Mr. H. Holt who has joined Messrs. Griffin as process representative.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### The Ozobrome Process.

Writing on the subject of "Fogged and Flat Ozobrome Prints," in "The Amateur Photographer," the Rev. Henry W. Dick gives the following hints to workers in the process. His conclusions are the results of tests on the prints, for the reproductions of which our contemporary must be consulted. (1) While a little alum added to the normal bath will serve to give a softer result from a hard bromide print, an excess of alum will produce flatness and fog. (2) That citric acid in small quantities will greatly lift the shadows without proportionately lifting the high-lights. In other words, it gives flatness. (3) That ammonia in small quantities will restore a bath that is working flatly through acid. (Ammonia will do the same for a bath working flatly through excess of alum.) (4) Excess of ammonia will produce harsh prints even from flat bromides. (5) A degraded bromide print will probably reproduce its degradation with interest. (6) Alum left in the film of the bromide will give flatness in the ozobrome.

### Notes on Sulphide Toning.

When a solution of sodium sulphide oxidises in the air (writes Mr. R. Child Bayley in "Photography") it is said that the change is first to sodium disulphide and to sodium hydrate, and, second, that some of the sodium disulphide is further oxidised to hypo. (Similar changes take place with ammonium sulphide, though not so readily.) It will be seen, then, that it is quite possible that hypo has been formed and is present in the sulphide solution applied to the bleached print if the sulphide solution was weak and badly kept. If it is further diluted the hypo may have time to act on the bleached image before the weakened sulphide has made it unattackable, and so the resulting tone may be altered. But only in this case. A solution of one part of pure sodium sulphide in a hundred parts of water allowed hypo to the extent of one-fourth the weight of the sulphide itself to be added without any change appearing in the toned print, but when the hypo was increased to one-half the weight of the sulphide, the print was slightly reduced in strength and was yellowed. The lesson of this is, of course, not to use too weak a solution of sulphide, and to keep the stock solution strong.

### Retouching and Finishing Bromide Prints.

"My method for mixing the paint for use" (writes Mr. H. A. Eaton in "Focus") "is as follows, and to do it effectually it must be done by daylight, not artificial light: First obtain some water-colour paints—say, a black, a sepia, and two or three tones of brown for brown-toned bromides, and other colours accordingly—and a No. 2 camel-hair paint-brush; then in a small palette make, with a little water, a mixture of the colours required to give the exact tone of the bromide print. Next add water until the paint is fairly weak, and having at hand a solution of pure gum arabic and water, of which a little may be kept for this purpose, or even ordinary office gum will serve nearly as well, dip the brush a sufficient number of times into it, and mix with the paint until the paint is perceptibly thickened. I find the gum necessary, as otherwise with such weak solution of paint the colour settles to the bottom.

## New Apparatus, &c.

The Taxiphote Stereoscope (for Verascope transparencies). Made by Jules Richard, 25a, Albemarle Street, London, W.

A most ingenious and convenient reservoir stereoscope may be seen and purchased at the new London establishment of the famous maker of the Verascope camera in Albemarle Street, within a door or two of the Royal Institution. The Verascope camera, we may perhaps mention, takes a plate 10.7cm. by 4.5cm.—*i.e.*, about 4in. by 1½in., and gives a negative which is extraordinarily sharp, even when obtained as a snapshot, owing to the short focus of the anastigmats used and the mechanical perfection and accuracy of the

workmanship of the instrument. No less admirably adapted to its purpose is the box stereoscope which bears the name at the head of this review, for it provides for the observation of an unlimited number of stereoscopic transparencies without once touching them with the fingers, while it is provided with adjustments, whereby the lenses are suited to the eye of the observer and the pictures changed by him by one pressure on the lever at the side of the case. Moreover, the instrument can also be used in projecting the transparencies.

These facilities owe their existence to a mechanism whereby each transparency is picked out of a grooved tray holding twenty-five of them, raised into the position for viewing, and returned, when desired, to its groove. Not only this, but by setting a lever and pointer any given picture of the twenty-five can be brought into position. When all have been looked at, the tray containing them is withdrawn and replaced by another in a second or two. As the case below the stereoscope proper accommodates

twelve trays each of twenty-five subjects, the apparatus provides its possessor with a series of 300 views, any one of which can be instantly removed or replaced by another.

In using the Taxiphot for projection, the ground glass which backs the transparency is removed, and any convenient source of even illumination—e.g., a condenser with arc light or limelight brought up behind the transparency—one of the viewing lenses then serving for projection. The conversion from viewing instrument to projection lantern does not call for any structural alterations to the apparatus, and the same remark applies to the use of the Taxiphot for enlarging from a Verascope negative. The price of the complete instrument is £10 12s. 6d.

Messrs. Richard will be happy to show the visitor to their elegant salon in Albemarle Street these uses of the Taxiphot and the accessory apparatus, projection lantern, and screen, which are supplied specially for use with it. Occasion should also be taken to examine at the same time some Autochrome transparencies made in the Verascope, which come very well through the ordeal of viewing with the magnifying stereoscope.

## New Materials.

Leto Vellum (Semi-matt) Bromide Paper. Made by the Leto Photo-Materials Company, Limited, 3, Rangoon Street, London, E.C.

In adding another variety of bromide paper to those sold under the trade mark of "Leto," the makers have chosen a surface which is largely in vogue just now on account of the partial sheen in the finished prints and of the generally rich effect obtained. The Leto "Vellum" is a paper which is excellent in these respects, and is equally satisfactory in its behaviour during development, giving prints of good black tone and all necessary brilliancy and purity of whites. The paper is obtainable at the standard prices and in the sizes specified in the Leto Company's recently issued new list.

## CATALOGUES AND TRADE NOTICES.

MESSRS. HARRINGTON BROS., LTD., of 4, Oliver's Yard, 53, City Road, London E.C., have issued a revised edition of their price-list of chemicals, which should prove both useful and interesting to those who use any description of chemicals either in large or small quantities. The firm also issue a special list of photographic chemicals, copies of which, as well as the general list, may be obtained free on application to the above address.

RAJAR (1907), LTD., have issued a new list of the Rajar photographic specialties in plates, papers, and chemical preparations. The list will be sent, post free, to any address on application.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, JANUARY 24.

Sutton Photographic Club. "Choice and Use of a Printing Process." Hector Maclean.  
West London Photographic Society. "The Camera at Home." E. T. Holding.  
Rotherham Photographic Society. *Amateur Photographers' Prize Slides*.  
Cardiff Photographic Society. "A Mixed Bag." A. McKinnon.

MONDAY, JANUARY 27.

Bradford Photographic Society. "Bird Life in Yorkshire." Riley Fortune, F.Z.S.  
Scarborough and District Photographic Society. "Volcanoes of Central America." Dr. Tempest Anderson.  
Catford and Forest Hill Photographic Society. "Making Transparencies." H. P. C. Harpur.  
Southampton Camera Club. "Some Spanish Scenes and People, and a Bull Fight." Arthur Marshall, A.R.I.B.A.  
Cleveland Camera Club. "Flower Photography." E. Seymour.  
Derby Photographic Society. "Orthochromatic Photography." T. A. Scotton.  
South Manchester Photographic Society. "Time Development." W. F. Slater.  
Muirkirk Amateur Photographic Association. Rotary Carbograph Paper.

TUESDAY, JANUARY 28.

Royal Photographic Society. "Suggestions on the Multiple Mounting of Photographic Pictures, with Examples." F. H. Evans.  
Nottingham Camera Club. "Switzerland: Glimpses of its Mountains." J. B. Wigfull.  
Jarrow Mechanics' Institute Camera Club. Photographic Chemicals.  
Manchester Amateur Photographic Society. Annual Meeting.  
Worthing Camera Club. "Theory and Practice of Enlarging." Edmund F. H. Crouch. "Lantern Slides by Reduction." Theodore Roberts.  
Keighley and District Photographic Association. "Brittany: Its Big Stones and its Queer People." Percy Lund.  
Rodley, Farsley and Calverley District Photographic Society. Conversations and Exhibition of Members' Work at Farsley Liberal Club.  
Leeds Photographic Society. "Some Avon Villages." Harold Baker.  
Hanley Photographic Society. "Competition Pictures, Lantern Slides, &c."  
Monklands Photographic Society. Rotary Carbograph Paper.

WEDNESDAY, JANUARY 29.

South Suburban Photographic Society. "X-Ray Photography." Demonstrated. T. Thorne Baker.  
Borough Polytechnic Photographic Society. "Our Commons and Open Spaces, their History and Preservation." I. W. Chubb.  
Coventry Photographic Club. "The Oil Pigment Process." J. Cawthood.  
Woodford Photographic Society. Auction Sale.  
Leeds Camera Club. "Walks and Climbs in Switzerland." Percy Lund.  
Edinburgh Photographic Society. "Printing Processes." Geo. M. Aikman.  
Central Technical College Photographic Society. "Demonstration and Examples of Cinematography." N. M. Clougher.  
Mill Camera Club. Debate. W. Richardson and L. Fearnley.  
Dennistown Amateur Photographic Association. Rotary Carbograph Paper.

THURSDAY, JANUARY 30.

London and Provincial Photographic Association. "Ozobrome." Thomas Manly.  
Handsworth Photographic Society. "Printing on 'Japine' Platinotype." A. E. Cope.  
Blenheim Club. "A Talk about the Cinematograph."  
Liverpool Amateur Photographic Association. "Criticism of the Annual Exhibition of Members' Work." Fred. V. Burridge, R.E.  
Bath Photographic Society. Practical Evening.  
L.C.C. School of Photo-Engraving and Lithography. "The Illustration of Books Historically Considered." R. A. Peddie.  
Richmond Camera Club. "A Summer Holiday in the Bernese Oberland." Dr. Rodman.  
Swadlincote and District Photographic Society. "Photographic Chemicals."  
Greenock Camera Club. Rotary Carbograph Paper.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, January 21, Mr. Leslie E. Clift in the chair. A lecture on "Westminster Abbey" was delivered by Mr. S. G. Kimber in his usual attractive and interesting style. The lecture was illustrated by a number of excellent lantern slides, showing Mr. Kimber's pictorial work in architectural photography to great advantage. A large audience testified its admiration of the many beautiful effects in lighting by frequent applause.

# THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEMBERS' meeting was held at the Royal Photographic Society on Friday, January 10, Mr. H. C. Spink, President, in the chair.

Mr. H. J. Comley, of Stroud, hon. secretary of the Society of Colour Photographers, delivered a lecture on "Colour Photography from a Professional Point of View," in which the question was treated, not only from a strictly commercial point of view, but the technical and general aspects were fully considered, and the necessity for special training for assistants, particularly for the printer, referred to. The lecture was followed by a demonstration, and two sets of trichromatic prints, a portrait and a still life study, made on Rotary stripping films, were developed and placed together, the method of transferring the prints to paper being fully described and shown.

**LEEDS PHOTOGRAPHIC SOCIETY.**—At the annual general meeting, held on January 14, the usual election of officers took place. With two exceptions there was no change. Mr. T. W. Thornton was re-elected president, and Mr. Robert Mackay, 69, Albion Street, Leeds, was elected secretary, in the place of Mr. J. Fielding. At the close of the business a fine selection of lantern slides was exhibited by Mr. Godfrey Bingley, who received a hearty vote of thanks at the conclusion.

**SOUTH SUBURBAN PHOTOGRAPHIC SOCIETY.**—Demonstrating ozobrome on Wednesday evening, Mr. Thomas Manly, the inventor of the process, emphasised the necessity of observing the prescribed time, temperature, and manipulation in carrying out the various operations. He gave the pigment plaster half a minute preliminary soaking in plain water, cleaning the surface under water with a soft Turkey sponge. Then he gave it two minutes in the pigmenting solution, face up as before, again sponging it gently before re-washing to remove the superfluous pigment. It was necessary also, he said, to see that the plaster was wider all round than the bromide print to be treated. In bringing print and plaster into contact the print was floated face up below the surface of the water. Then the pigment plaster, face down and slightly bent, was brought into contact with the water, at the upper end (farthest from the operator), and gradually and gently lowered with a sliding motion to avoid air-bells. The two were not pressed together. They were nipped between forefinger and thumb at the further edge, and quickly raised together by that edge, and allowed to drain before being gently squeezed into contact with a flat squeegee on a piece of plate glass. They were left in contact fifteen to twenty minutes before developing. Canon Barnes-Lawrence (chairman) and Rev. R. J. Swinnerton (timekeeper) were keenly interested, and asked numerous questions as to details.

## Commercial & Legal Intelligence.

**CLAIM FOR A PHOTOGRAPH.**—At the Dartford County Court last week, James Berry, a silk printer, of Mount Pleasant Road, Dartford, claimed of Messrs. A. and G. Taylor, photographers, of Victoria Street and Regent Street, London, £1 for the return of a photograph or its value, and 30s. for money paid.

Plaintiff's case was that he gave an order to an agent of defendants for an enlargement of a photograph, and had paid 30s. by instalments to the agent. The photograph was at the time in the possession of a similar firm, and Messrs. Taylor's agent informed plaintiff that, with his authority, he (the agent) could obtain possession of it. The authority was given and the photograph obtained; but now plaintiff was informed that it had been lost. The defendants wrote that they were informed by their agent in question (Mr. Hewitt) that he had obtained the portrait, "but we have never received it." The result was that plaintiff had now neither the photograph (that of a child of his who had died) nor the money.

Defendants' manager said his firm did not dispute the claim for the return of the money; but they contended that the original photograph was never in the possession of them or their agent.

His Honour: How can you say it was never in your possession when you wrote that you were informed Hewitt had obtained the photograph from a firm in Newington Causeway?

The Manager: That was his statement.

His Honour: He was your agent.

Judgment for the amount claimed, with costs.

**DAYLIGHT DEVELOPMENT.**—On January 16 Mr. Justice Barker had before him the action of the Standard Patents Co., Ltd., v. Kodak, Ltd., by which the plaintiffs claimed an injunction in respect of an alleged infringement by the defendants of their patent for an invention for the development of photographic films.

Mr. Buckmaster, K.C., and Mr. Macklin appeared for the plaintiffs, and Mr. Walter, K.C., and Mr. Kerley for the defendants.

In opening the case Mr. Buckmaster said that both the plaintiffs and defendants were limited companies. The defence to the action was the common one. The defendants denied infringement, denied that the letters patent were good, and set up a series of alleged anticipations, a very large number of which he did not suppose the defendants would deal with at the hearing. Counsel went on to explain that, in photography, when the image had been taken through the camera, three processes had to be followed. The negative had to be developed, washed, and then fixed. The way that was done for many years was to place the plate or film in an open trough in a dark room illuminated only by a red or yellow light. There were several objections to the open trough, amongst which were the difficulty of manipulating the films in the light, the trouble and nuisance of consistent observation, and the risk of the negative being spoilt by dust or air bubbles. The invention in respect of which the plaintiffs claimed was an invention which, they said, for the first time enabled the development to take place without the necessity of observation or manipulation or the protection of a dark room with a red or yellow light. The plaintiffs had, in fact, invented a process by which development could take place in the daylight, and no superintendence was required. The defendants had an old machine for developing, which was brought out in 1902, but the plaintiffs contended that it was nothing like their invention, and their case was that the defendants had now deliberately infringed their patent, and in order to protect themselves had, in 1905, patented what was really the plaintiffs' invention. Expert evidence having been called in support of the plaintiffs' case, Mr. Buckmaster said that after consultation with his junior and his client, he had come to the conclusion that, on the narrow construction put upon the patent by the experts, he could not argue that the defendants had infringed. He, therefore, consented to having the action dismissed, with costs. His lordship made an order accordingly, and upon the application of defendants' counsel, certified that the objections taken to the patent that were dealt with were reasonable.

**BRITISH MUTOSCOPE AND BIOGRAPH COMPANY.**—At the London Bankruptcy Court on Tuesday a meeting of the creditors of the British Mutoscope and Biograph Company, Ltd., took place. The winding-up order was made on November 19. The Official Receiver stated that there were 145 unsecured creditors, whose claims amounted to £21,308. Loans on debentures amounted to £32,060. The assets were returned at £30,000, including investments and shares, £19,500. There were not quite enough assets to satisfy the claims of the debenture holders, so that there would be nothing available for distribution amongst the unsecured creditors or shareholders. The total deficiency was returned at £274,705. The company was registered on January 23, 1899, with a capital of £300,000, to acquire the assets of the Mutoscope and Biograph Syndicate, Ltd. The syndicate had previously formed ten subsidiary companies for the purpose of carrying on similar businesses in different parts of the country. Each of the companies entered into an agreement to hire machines from the syndicate. The Mutoscope Company paid £240,000 in cash for the assets of the syndicate. The company was for a time very successful. For the year ending February 28, 1900, the profit was £28,451; in 1901, £11,822; and in 1902, £839. Since then there had been continuous losses. The failure of the company was attributed to the public interest in a novelty having declined. Mr. Smedley, the late chairman of the company, admitted also that there might have been some mismanagement. In November, 1907, arrangements were made with the debenture holders that, in consideration of being paid in full, they should purchase debentures in a new company, the Bio-Trust, Ltd. The result was that there was nothing to liquidate, as all the assets had been sold to the new company. The meeting decided not to apply to the Court for the appointment of a liquidator, but to leave the winding up of the company in the hands of the Official Receiver.

**"FREE PORTRAITS" IN THE COUNTY COURT.**—At the Pocklington, Yorks, County Court on January 18, the King Edward Fine Art

Enlarging Co., of 65, Louis Street, Chapeltown, Leeds, sued E. Judson for £1 2s. 6d. for a photographic enlargement, and a similar claim was made against — Simpson for 12s. 6d. Mr. Summerson appeared for the plaintiffs, and asked for an adjournment on the ground of the illness of a witness. Mr. Powell, for the defendants, opposed the application unless the costs of the day were at once paid into court. The plaintiffs' solicitor having declined to do this, Sir Horace refused the adjournment, and as defendants and their witnesses were present, and the plaintiffs' solicitor was unable to prove his case, his Honour gave a verdict for defendants in each case with costs. In the course of the case his Honour asked the plaintiff's solicitor if he had been paid his fee, and on his replying in the affirmative, significantly remarked that he was lucky.

The facts of the case against E. Judson, which he was prepared to prove in court, are as follows:—The wife of the defendant was called upon by a woman canvasser, who represented that an enlargement would be made, as an advertisement, absolutely free of charge, but if she liked a frame it could be supplied much under the usual price. Mrs. Judson agreed to accept the enlargement, but said she could not afford a frame. She was advised not to tell her husband anything about the matter. In course a man brought the enlargement already framed, and persuaded Mrs. Judson to pay 2s. 6d., but no agreement was made for any further payments, and on the matter coming to the husband's ears and his repudiating liability, the summons was issued.

**WAITING FIVE YEARS FOR A PHOTOGRAPH.**—The story of how a Newhall labourer waited for five years for his photograph to be taken was brought to the notice of Judge the Hon. Walter Lindley at the Burton County Court, sitting on January 16, when a man named Plummer and his wife, of Newhall, sought to recover from Messrs. Taylor and Co., photographers, of Derby and London, the sum of 32s., the amount paid in anticipation of their having their photographs taken.

From the evidence it appeared that the contract entered into by Plummer, his wife, and the firm's representative was that by paying the sum of 35s. in instalments they were to have their photograph taken and have one large copy on china and six cabinet size. The arrangement was made in September, 1902, and although they had paid 32s., no one had ever come to take their photograph, and when they went to Derby for a sitting they were told that the firm had left the town and gone to London. They never heard anything further, and although they wrote to London no reply was ever received.

Mr. Leicester, the firm's representative who defended the action, said a photographer called on the people, but they would not have their photographs taken then because Mrs. Plummer was ill. They could have their photographs taken now if they wished.

The Judge: It is very likely that they won't want to do that. This contract was drawn up five years ago, and although the photographs might have been required then, it does not follow that they are wanted now.

Mrs. Plummer said the photographs were not required now. They preferred their money back.

His Honour said that he had come to the conclusion that the defendants had not fulfilled their part of the agreement, and he ordered that the 32s. be refunded, with costs.

## News and Notes.

**AN "OIL" EXHIBITION.**—An exhibition of photographs by the oil process will be opened at the Liverpool Amateur Photographic Association's rooms, 9, Eberle Street, on February 6. There will be no charge for admission, and the exhibition will remain open till February 22.

**LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.**—That this northern photographic club continues to occupy the high position it has so long maintained amongst photographic societies is evidenced both by its annual report and by the excellence of the photographs now on view at its exhibition of members' work, which will remain open at the society's rooms, 9, Eberle Street, until February 5. At the annual meeting held last week the reports of both secretary and treasurer showed a continuance of progress and prosperity, and in

the course of a short address the chairman, Mr. F. Gregory Jones, complimented all concerned in the management of the association on the satisfactory result of the past year's work. The officers elected for the ensuing year are: Mr. F. Gregory Jones, president; Mr. J. Dudley Johnston and Colonel A. Grimshaw Haywood, vice-presidents; Mr. Charles F. Inston, F.R.P.S., hon. secretary; Mr. Wm. Lockier, hon. treasurer; and Mr. W. A. Taylor, hon. librarian. Dr. John Ellis and Messrs. J. W. Towers, T. E. C. Wilson, Harry Holt, W. B. Hellon, Lawrence Rea, and Charles F. Stuart were elected on the council.

**PORTSMOUTH CAMERA CLUB.**—This club, which is the outcome of a thorough reorganisation of the old and well-known Southsea Photographic Society, has just got its new officers into harness. With a now popular subscription of 7s. 6d., instead of the former exclusive guinea, a newly decorated suite of rooms, and a staunch executive, who intend to leave no stone unturned which will make for success, things photographic in our premier naval port should give evidence of an abounding vitality which has of late been wanting. The following gentlemen compose the new body of officials:—President, Colonel Johnstone, C.B.; vice-president, Mr. W. H. Barrell; hon. treasurer, Mr. J. Cromwell Prior; hon. secretary, Mr. F. J. Lawton, 20, Clarence Square, Gosport; assistant hon. sec., Mr. W. H. Dugan; committee, Messrs. A. B. Casey, S. Dawe, and J. C. Thompson. The recent exhibition has fortunately proved a financial, as well as an undoubted artistic, success.

**THE SCOTTISH PHOTOGRAPHIC SALON.**—Since the issue of the prospectus a month or two ago, the local committee have been busy, and arrangements are now well advanced for the opening of the exhibition in the Art Gallery in the middle of February. By that time the committee expect to have on the walls a large and representative collection of Scottish work. In addition to the main body of exhibits, there are sections for work sent in by special invitation of the committee, and the selected specimens of English work which have been promised by Mr. J. C. S. Mummery, president of the Royal Photographic Society, will doubtless add much to the value and interest of the exhibition. A more technical aspect will be presented by a series of illustrations of the recent progress of colour photography, the exhibits in this section being sent by Mr. Henry J. Comley, secretary of the Society of Colour Photographers. Another feature of special interest will be a natural history exhibit, arranged by Mr. H. Armytage Sanders, F.R.P.S., which will include works by the leading field naturalists, who, by the aid of the camera, have done so much during the past few years to make natural history popular.

**DISSOLUTION OF PARTNERSHIP.**—The partnership between Louis Smith and Percy John Swain, photographers, carrying on business at 2A, Davey Place, and Burlington Buildings, Orford Place, Norwich, as "Louis Smith and Co.," has been dissolved by mutual consent.

**COLOUR WORK IN LEEDS.**—Mr. Henry J. Comley will lecture to students of the photo laboratory, Leeds Central Technical Schools, on "Colour Photography," and give a practical demonstration of tri-colour carbon on Friday, February 7, 1908, at 7 p.m. in the Chemical Lecture Theatre. Friends desirous of being present should communicate with Mr. S. E. Bottomley, F.R.P.S., Central Technical Schools, Leeds, as accommodation is limited.

**BARGAINS IN BACKGROUNDS.**—Messrs. O. Sichel and Co. announce that a post-stocktaking sale of high-class American and other backgrounds enables them to offer a number of these accessories at very moderate prices. The grounds can be seen at 52, Bunhill Row, E.C.

**FIRE IN BELFAST STUDIO.**—A slight outbreak of fire occurred on the premises occupied by Messrs. Frost and Kelly and others, photographers, 3, High Street, shortly after eight o'clock on January 17. The damage to the room on the top storey, to which the fire was confined, was slight.

**EXIT THE "PHOTO-AMERICAN."**—Regret can scarcely be expressed at the news of the demise of our contemporary, the "Photo-American," which, since the death of its former editor and proprietor, Mr. Ed. Newcomb, has been conducted by his widow on the same comfortable plan which for years past has filled its pages with articles "lifted" without acknowledgment from the British periodicals. A publication of this type can easily be spared.

## Correspondence.

We do not undertake responsibility for the opinions expressed by our correspondents.

Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

### A TELEPHOTO CALCULATOR.

To the Editors.

Gentlemen,—In this day's Journal I see my letter on a Telephoto Calculator, and wish to point out a mistake, as other correspondents are sure to do so if I don't.

The equation (as given in the proof you sent me) is  $x = \frac{y}{a} + 1$ , which

correctly that of a straight line; while the equation as given  $y = \frac{a}{x} + 1$ , is not that of a straight line but of a hyperbola,

terms  $a$  and  $y$  having been inverted. I suppose those who read your letter will themselves correct what is merely a printer's error. It may prove useful to others as it has done for myself.—

Main, yours faithfully,  
D. Hungerford Road, Crewe.  
January 17, 1908.

A. THOMAS.

## Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

Waine, Bushy Cottage, Park Road, Teddington. Three Photographs of the *Leam and Office-builders*, St. Alban's Church, Teddington.  
Hughes, Cerrigydruidion, Corwen, North Wales. Photograph of Colonel C. S. *Wainwright*.  
Glanville, 1, Sutton Road, Southend-on-Sea. Two Photographs of the Rev. *Wm. Butterworth*.  
Perkoff, 136, Commercial Road, London, E. Two Photographs of *Efrem Ambalst*, the famous Russian violinist.

### DRAWING REGISTERED:—

Wilmington, 1, Aigburth Hall Road, Aigburth, Liverpool. Drawing of *Old Cottage*, "Frog Hall," Grassendale, Liverpool.

QUESTIONS IN U.S.A.—(1) Would you please inform me the average rate per week of operators' and assistants' pay in Canada and the United States? (2) Is business in a better condition than in England? (3) What would be the best way to get a situation there, by advertising, what journal, also their charge for advertisements?—EMIGRANT.

(1) It varies as much as it does here. (2) We believe business more satisfactory in Canada at present, but somewhat unsettled in the States. (3) You had best try the "Bulletin of Photography," 98, Sansom Street, Philadelphia.

FORMULA.—Many thanks for reply in this week's "B.J." re mean developer on page 43 "B.J." for January 18, 1907. You gave me the pyro-soda one, but it is the metol hydroquinone for gas-

light and bromide I want, on page 44 of above date's issue, the last one on page 44. Please give it in British measures for a convenient quantity, and say what proportion of water goes with the solids in above lists, as I am not quite clear about it, water being omitted in that list.—THISTLE.

As stated in the earlier part of the article, the figures are "parts per thousand parts of water," and if halved are, roughly, "grains per ounce of water." A more exact translation of the last formula is:—

Metol .....	25 grs.
Hydroquinone .....	45 grs.
Sodium sulphite .....	1 oz.
Sodium carbonate .....	500 grs.
Potass bromide .....	6 grs.
Water .....	20 ozs.

PINATYPE.—Could you kindly inform me where I can obtain the materials, etc., for working the pinatype colour process?—AN OLD READER.

Fuerst Bros. See our advertisement pages.

R. W.—There are several advertisers of these articles in our outer pages. Try Griffith's Steam Works, 26-31, Eyre Street Hill, Hatton Garden, E.C.

REFLECTOR.—Will you please suggest a reflector for portraiture in a sitting-room? Also what is the best reflecting medium?—REFLECTOR.

A very suitable reflector is a light wooden frame, 5 or 6 ft. by 4ft. or 5ft., on which is strained a piece of white or pale blue calico. But almost any light thing will do. A tablecloth, or sheet, on a clothes-horse is very frequently used, and is about as good as anything.

PROSPECT.—The articles to which you refer appeared in our issues for March 15, 22, and 29, 1907.

R. E.—No. 2,304, 1903, in the name of F. Kollmorgen.

SULPHIDE-URANIUM TONING.—I find for some subjects very effective tones can be attained by placing a sulphide-toned bromide into a uranium toning-bath. By this process the whites stain to an effective brownish colour. The shadows darken and richen up so that when waxed a superbly rich print results. Are prints thus treated likely to be very liable to fade when framed?—S. E.

We have no experience of such prints, but we cannot suppose that they are more satisfactory as regards permanence than those toned only with uranium—probably they are less satisfactory—that is to say, they are liable to "go off" or darken in a time which may be a year or two or only a few months.

PROGRESS.—We are unable to give you particulars of the secret process, nor do we know the present whereabouts of the inventor. Messrs. Raines and Co. might be able to tell you.

PHIKAPPA.—Both lenses are of high quality. It would be misleading to draw comparisons between them.

FIXED FOCUS.—I should be glad if you would give me your advice on the following point: I have two fixed-focus hand-cameras, the lenses of which I am desirous of obtaining the exact range of focus. The makers of the cameras are unknown to me, and the dealer.—A. O. PULFORD

In each case measure the focal length of the lens and divide by the diameter of the diaphragm aperture. From these two factors, focal length and working aperture, you can ascertain the distance of the nearest sharp object from a table such as that on page 960 of the present "Almanac."

P. O.—The article appeared in our issue of November 22, 1907.

THREE-COLOUR CARBON.—1. As I am wishing to work this process commercially, I would like to know first: (1) Whether there are any patents or restrictions in connection with working same, as I noticed not long ago in the "B.J." some person had patented a method of using the above process by stripping from collodionised glass plates. (2) Is there any restriction against working any of the existing colour-processes of to-day?—W. W. W.

There are none. Any rights are invested in the manufacture of the materials, and are conceded on the purchase of the latter.

RETOUCHING (Reply to C. E. S.).—The retouching shown on your specimens is carefully done, but very insufficient, and miles away

from the best-grade work; but there is no reason why you should not attain high quality skill in the art. Better take a few lessons from an expert teacher. Retouchers who are not also professed and experienced teachers may advance you to a certain stage, but you are more likely to benefit from experienced tuition such as you can find announced in our advertising pages.

**MARKING MOUNTS.**—Will you kindly give the name of a really good die cutter? We had one made—to use as a punch—with our name, but it is so poor that a heavy blow is necessary to make an impression on mounts, and only a faint mark then.—**LIMERICK.**  
Messrs. Houghtons supply dies for impressing photographic mounts. You will find the names and addresses of die cutters in the "Post Office Directory." Whatever die you have will require a somewhat heavy blow, if the mount is hard and thick, to obtain a deep impression. The best way of using a die is in the usual lever die press, and not with a hammer.

**THOS. F. FAIRFIELD, SAM JONES, and others.**—In our next.

**WOOD STAIN.**—I should be much obliged if you would give me a recipe or formula for a staining mixture to darken oak frames, so as to make them harmonise with sepia brom. enlargements. I do not want anything in the nature of varnish, but I believe there is a mixture of bichromate of potash and something else. If you can help me in this matter I shall be much obliged.—**PHILIP S. HEDYSLANT.**

The formula you inquire for is probably one such as:—Bichromate of potash 1 oz.; water, 20 oz. Another is:—Bichromate of potash, 1 oz.; Vandyke brown, 4 oz.; liquor ammonia, 20 oz. Either of these give a good brown stain on oak. We should recommend you to try both, and see which gives the colour you like best.

**RIGHT TO SELL.**—I am in the habit of going to the villages around here and taking a set of views and houses of interest for photographic postcards. These I supply to one shopkeeper in the said village to sell again for me, reserving, of course, to myself the right to sell separately if I wish, or get an order. The other day, when taking a set of a certain village, I photographed an old farmhouse, and to give life to the photograph I got the son and daughter to stand outside. They afterwards purchased direct from me twenty-one of the postcards at the shop-selling price, viz., 2d. each, and also three half-plate copies at the same shop-selling price, viz., 1s. each. After supplying them with these, I let the shopkeeper have six postcards of the said farmhouse to sell again, in with his batch of postcard views of the village. I have now this morning received a letter from the farmer's daughter saying that she finds the postcard views of their place are being offered for public sale in the village. She is very much annoyed at it, and unless I at once not only stop the sale of them, but also get back what have been already sold, they shall take proceedings against me. Will you now oblige me by informing me whether I am liable or not, and whether I am bound to stop the sale and get those back? I am quite ready to please them by doing so, but I do not like receiving threatening letters; and I should be glad if you would let me know.—**BERT HOLE.**

It is a nice point, but it seems to us that you solicited the customer, and were paid for taking the pictures, therefore you have no right to sell copies against their will. The copyright is invested in the customers. They can certainly stop the sale if they put the law in force. Would it not have been more to your interest, from a business point of view, to at once have withdrawn the pictures from sale, and apologised to the customer, rather than raise any question as to your supposed rights?

**OPENING STUDIO.**—Is it possible to open a middle-class business (and be successfully continued by two) for £50 and £25 capital, working by artificial light, and finishing in matt and glossy, black and sepia bromide, or would P.O.P. have to be introduced?—**C. C. MATHER.**

This is a question that no one can answer so well as you and your partner can, as you must know your business abilities better than we can possibly do. We should say, however, that if you have to build a studio, install artificial light, and provide apparatus, accessories, etc., you will have but little working capital left. We assume that you have but a limited knowledge of practical

photography, or you would know that there is but little difference between bromide papers and P.O.P.

**G. J. CLARKE.**—The "Colour Photography" Supplement has appeared without exception with the first issue of the "B.J." in each month during the past year.

**JAPANESE VELLUM PAPER.**—1. I notice mention of this paper on page 40 of last week's issue, January 17. Can you inform me where I can obtain it? 2. Which is best for carbon, the thick or thin paper?—**C. P. M.**

See answer to "All Kapteyn," under "Japanese Paper."

**JAPANESE PAPER.**—I was much interested in reading your article on carbon printing in your No. 2,489, and have often wished to obtain the Japanese vellum papers referred to. Would you kindly state in your correspondence column where these can be obtained retail, and which kind is most suitable for transferring the carbon print on to, and oblige.—**ALL KAPTEYN.**

The agents for the paper are Messrs. Crompton Bros., 2, Queenhithe, London, E.C. They issue a book of samples of about twenty different substances and surfaces, any one of which can be used for the carbon pictures, and it is quite a matter of individual taste as to which is best. We are not sure that this firm supplies the paper in retail quantities. Better communicate with them.

**JERNY.**—Certainly the lens can be divided, as the separate components used as lenses of longer focus. We should call the lens a suitable one for all-round work.

**BISULPHITE LYE.**—Would you be good enough to tell me the meaning of sodium bisulphite lye, which appears in a formula on page 687 in the "B.J. Almanac."—**T. KEYSSELL.**

A strong solution of "sodium hydrogen sulphite," or "sodium acid sulphite," as it is more commonly called. A special preparation for photographic purposes is sold by the Lumière N.A. Co.

**C. R. WILTON.**—We should say that the matt surface opal plates with polished bevelled edges will best answer your purpose. They are stocked by all the large dealers, such as Houghtons, Marion's, and others. They are very inexpensive.

**G. CONNOR.**—Copper and zinc plates suitable for photo-engraving are supplied by Messrs. Penrose and Co., 109, Farringdon Road, E.C.

**MR. PONTING'S PHOTOGRAPHS OF JAPAN.**—The Japan "Daily Mail," in a recent issue, refers to the collotype reproductions by Ogawa of the photographs of Fujiyama and other notable scenes in Japan by Mr. H. G. Ponting, who is at present in London. Our Japanese contemporary describes the photographs as "the most beautiful reproductions of Japanese scenery and life we have ever had the great pleasure of viewing. They are quite free from the objectionable characteristics which belong to the ordinary photograph: offensive fidelity, mechanical accuracy, and exclusion of all appeal to the imagination."

**NEWMAN AND GUARDIA, LTD.**—In our notice of this firm's new catalogue in last week's issue we omitted to state that all applications for same should be accompanied by a remittance of three penny stamps.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The exhibition of portraiture by members of the Professional Photographers' Association opens at the house of the "British Journal" on Thursday next, and will remain open until March 7 daily from 10.30 to 4.30; Saturdays 10.30 to 12.30.

Mr. Frederick H. Evans' exhibition at the R.P.S. of multiple painting is a thing not to be missed. Mr. Tilney's review of it appears on page 87, and a report of Mr. Evans' opening lecture on page 91.

Mr. F. W. Speaight's scheme for the improvement of the roadway of the Marble Arch and the separation of the Arch from Hyde Park, was on Tuesday last formally adopted by the London County Council, with expressions of compliment to Mr. Speaight for his suggestion of the scheme. (P. 83.)

Some corollaries which must follow the assumption of professional rank by a photographer are the subject of some notes on page 80.

Useful awards at exhibitions, the Kallitype process, and printing vignettes by artificial light, are topics of general interest in our "Correspondence" columns. The status of the professional photographer, copyright in postcards, and the stamping of mounts, are of more professional interest. (P. 93.)

Mr. Blake-Smith recommends the thiocarbamide bath for the after gold toning of sulphide-toned bromides. (P. 88.)

We regret to record the death of Mr. H. S. Mendelssohn, one of the best-known professional photographers. (P. 86.)

We review Dr. von Rohr's exhaustive treatise on binocular instruments. (P. 88.)

A Study of Orthochromatism.—The first portion of the paper by Mr. R. J. Wallace describing sensitometric experiments on the use of the newer sensitizers commences on page 83.

Some comments on the behaviour of agar as a vehicle for silver salts in the making of emulsion papers and plates appear on page 9, in further reference to the communication of Messrs. Cooper and Nuttall to the R.P.S. recently.

## EX CATHEDRA.

### The Barnsley Disaster.

A contemporary remarks that in view of the Barnsley and other disasters one cannot help commenting on the fact that the cinematograph is indirectly responsible for the loss of many lives. Why Barnsley should be mentioned in this connection we are at a loss to imagine. The principle of giving a dog a bad name need not be followed by the photographic press when referring to the cinematograph, and though some serious calamities did happen in the early days of "living pictures," the Barnsley fatalities were not in any way due to the fact that a cinematograph was in use. The proposed entertainment might have taken any other form. A Punch and Judy show would most likely have attracted as big a crowd of children, and in the same absence of proper supervision the same disaster would have probably occurred. As a matter of fact most of the fatalities that have occurred at cinematograph entertainments have been due to panic when there was little or no real danger. Under the regulations now observed in most places there is no danger whatever to the audience, even if a film catches fire. Panic is the only real danger, and senseless remarks with regard to the responsibility of the cinematograph for the loss of many lives suggest danger where there is none, and thus serve to encourage further panics.

\* \* \*

### The P.P.A. Exhibition.

The collection of some hundred examples of portraiture by members of the Professional Photographers' Association, which will be opened for inspection on Thursday next, will be found to contain much from which the rank and file of the profession may expect to learn. We shall refer next week to the exhibits in detail, but now we must not omit a reference to the somewhat melancholy interest arising from the death of two exhibitors, both members of the P.P.A. committee, and responsible in some measure for the exhibition. The removal by death of Martin Jacolette and H. S. Mendelssohn has deprived photography of two professional workers, both of whom were original in use of the photographic processes and set a standard of work before themselves which they persistently studied to raise.

\* \* \*

### Distortion in Lenses.

The article by Dr. Wandersleb, of the Carl Zeiss scientific staff, which appears on another page, will suggest to the serious reader an explanation of things which at times may have puzzled anyone with even a fair acquaintance of photographic optics. We have heard of instances where a lens has been returned to the maker with a complaint of serious distortion which the maker was quite unable to discover in the lens. It was afterwards found that when making tests on a different

scale of reduction the distortive properties of the lens were very pronounced. The discrepancy arose from the different circumstances in the two cases. The maker's test was an indoor one on a fairly close test-chart; the users, out of doors, on a distant object. The lens which showed the phenomenal difference implied by the above description was a unique specimen, and if our recollection serves us correctly, no explanation of its behaviour was discovered. Dr. Wandersleb's curves, however, show that such a thing exists in a more or less modified form in almost all lenses, although in the case of a great many the defect is negligible.

\* \* \*

#### Failure Of the Reciprocity Law.

Herr A. Werner points out in the current issue of "Zeitschrift für Wissenschaftliche Photographie" that the Bunsen-Roscoe reciprocity law, according to which—calling  $E$  the exposure,  $I$  the intensity of the light, and  $t$  the time of exposure— $E=I t$ , does not hold good with colour sensitive plates. The failure of this law was first pointed out by Abney in 1893, and was confirmed by Schwarzschild, Eder, and Englisch. It was dealt with at some length by Mees and Sheppard, but in all cases the ordinary non-colour-sensitive plate was under consideration. Schwarzschild proposed the formula  $E=I t^P$ , in which  $P$  is less than unity. The light source used by Werner was a controlled osmium lamp with a yellow screen. The plates were exposed in strips at varying distances for varying time and the densities obtained on development measured. The results proved that the value of  $P$  varied with different brands of orthochromatic plates from 0.78 to 0.85. It was also found that within wide limits the concentration of the developer has no marked influence on  $P$ , but that temperature and duration of development were of marked influence, and the higher the temperature and the longer the duration of development, the greater the failure of the reciprocity law or the less the value of  $P$ . The practical effect of this is that in stellar photography the use of colour-sensitive plates is hardly advisable, because although the plates may be specially sensitised for the particular light of the star, yet the increase of exposure necessitated by the small value of  $P$  does away with any possible advantage as regards cutting down the exposure.

\* \* \*

#### Early Photography

The "Times" of Friday last prints a letter from a Dr. Eric Pritchard under the very misleading title, "The Date of the First Photograph." The reference is to the negative of the Slough telescope made by Sir John Herschel in 1839, a few days before the telescope was dismantled. The writer, in referring to a photograph which came into the possession of his father in 1890, is evidently writing of a copy of the original Herschel negative, and a reproduction of Herschel's description of its production, which was prepared by Sir William Herschel and has been presented by him to various friends. Interesting as this souvenir is, it should not be confused, as the heading to Dr. Pritchard's letter confuses it, with the "first photographs."

\* \* \*

#### Photography and Criminals.

Some idea of the great importance which the Continental police authorities attach to photography as a means of tracing criminals and bringing them to justice may be gathered from the annual report of the Berlin detective department, which is just published. During the year no less than 1,544 persons were photographed in the private studio attached to the central police buildings, and 404 photographic copies were made from photographs or sketches

of suspects. To different police authorities on the Continent and abroad 59,314 prints from these photographs were sent, as against 45,950 during last year. But of much greater interest is the fact that the exact results obtained by these photographs are also published, and they fully prove the great value of this interesting department. The photographs, as is already well-known, are collected into what is called the Criminal Album, and they led to the arrest of 176 criminals, while by exhibiting copies in public places other seven "wanted" characters were brought to justice. It would be interesting to compare these figures with a report coming from Scotland Yard showing what part photography has played in the prevention of crime in England, though we believe the photographs are found less valuable by the English authorities than finger-print records.

\* \* \*

#### Playertype

Dr. Friedburg, of New York, states, in the "Photographische Korrespondenz," that he tried to obtain the images of scratches on a metal plate on a dry plate by contact in the dark for several weeks without success, and concluded that light played some part in the effects that had been obtained. A daguerreotype was then placed in contact with a plate and the plate exposed to diffuse daylight. When the correct exposure was hit upon, a faint positive of the daguerreotype image was obtained. Starting from this point, Dr. Friedburg tried to obtain images of printed matter, pictures, etc., and succeeded. The theory of the process is not clear, nor has any satisfactory explanation been given of the results obtained by Mr. Hort Playon on bromide paper. Dr. Friedburg suggests that it might be possible, by using a Lippmann plate, to obtain heliographic results.

\* \* \*

#### Free-Sitting Business.

The method of attracting sitters to the photographer's studio which is based on the offer of a sitting, or a portrait, for nothing, is one which we have often referred to as exerting an injurious influence on the entire portrait business, even though it may be a necessary expedient in some West-end establishments. But if it is to be adopted at all it surely needs to be put into practice in a less half-hearted way than is the custom with some studios. His interests outside of photography having led the editor of the BRITISH JOURNAL to become a member of several societies, it is his experience to be the recipient of offers from photographers, who would have him believe that the uppermost desire of their hearts is to prepare a complete series of portraits of the members of the So-and-so Society. To suppose that members of such societies as are approached in this way take this seriously is to put a value on human intelligence which may or may not be merited, but the point we would wish to suggest to some of those who adopt these methods, is that they ought at least to offer something more than the sitting. A recent circular does not even promise to repay the invited person for his trouble with a print, in which case it might be difficult for the photographer to establish proprietorship in the copyright.

\* \* \*

#### Stains from Farmer's Reducer.

The suggestion has recently been made that the stains met with by some workers when using Farmer's reducer of hypo and ferricyanide are due to developer left in the film, but this seems to us rather a far-fetched explanation. It is far more likely to be due to the imperfect removal of the silver compounds formed during the action of the reducer. Any developer would very probably cause stains of a sort, but

the ordinary process of fixing we doubt if any developer remains in the film, while it is pretty certain that it can remain after fixing and washing. An imperfectly fixed negative will show stain owing to the reduction by light of the silver-hyposulphite compounds left in the film, and we may expect a similar result when any of the products of the action of Farmer's reducer remain. Our own experience is that stains do not appear if the reducer is followed by a plain hypo fixing bath, and it is invariably our practice to adopt this second bath. If this suggestion fully explains the stains we may expect that a reducer strong in ferricyanide and weak in hypo will also be likely to produce them, while one weak in ferricyanide and strong in hypo should be less likely to do so. It should be remembered that very similar stains are often produced with other reducers, such as persulphate, and the after use of a fixing bath seems to us to be advisable in all cases.

\* \* \*

# **Enlarging Carriers.**

Of late we have been compelled to do a considerable amount of enlarging and to deal with several types of enlarging lanterns, and, among the minor troubles we have met with, unsuitable carriers have been the most annoying. In two entirely different lanterns we found the same defect. The carrier was the wrong way round, and it became necessary to re-focus every negative used owing to the fact that the back of each negative, and not the film, fell into register. Such a ridiculously simple fault suggests that the designers of these lanterns could not have had much practical experience in enlarging, otherwise they would have known that it is a very great advantage to be able to rely on a carrier when it has once been obtained with a suitable test plate. No constructive difficulty whatever interferes with arranging that the carrier shall be the right way round at the start, but it is not always easy to put things right after the manufacturer has once put them wrong. In neither of the cases we met with was the carrier reversible, though this very simple arrangement is a very useful one when reversed images are required. In fact, both instruments seem to have been designed for making reversed enlargements only, and not for direct enlargements at all. A second equally irritating defect in the provision of carriers that have no means of holding the negative firmly in register. This fault did not exist in one lantern, but it was prominent in the other, and it is a very common one in the majority of the lanterns we have seen. Turn-buttons are usually provided, but they are obviously useless to hold thin plates in a deep rebate, and as a consequence it is generally necessary to wedge up the negative with matches or paper pads. Spring clips are essential, but we seldom see them provided by the manufacturer.

# **AGAR-AGAR IN THE MANUFACTURE OF PHOTOGRAPHIC PAPERS AND PLATES.**

The paper by Messrs. Cooper and Nuttall, printed in *extenso* in our last issue, may be of such importance to the commercial point of view as to warrant a few notes hereon. It at least opens up a field for experiment, which may be rich in results and constitute an advance in practical photography as did the introduction of gelatine.

The authors, unlike many writers, seemed to have prepared no trouble in their researches as to prior publications on the subject, and yet, curiously enough, have entirely missed any photographic references. The possible explanation of this is that as chemists they naturally turned

to chemical literature. Mr. Paymaster Mitchell, R.N., in 1882, was the first to suggest agar-agar for emulsion work in tropical countries. A year later Dr. Stolze stated that when mixed with gelatine agar separated out into small lumps free from the silver halides of the emulsion. In 1890 Rebikow took out an English patent for the use of agar, and suggested therein the repeated heating and cooling of the agar in water, and the separation of the insoluble particles by decantation. A recent patent claims the preparation of a solution by means of a digester.

The authors have said so much in their paper that practically we can only point out possible modifications of their procedure, which tend rather to the saving of time than to improvements. If a solution of agar is made and then allowed to set it will be found that a considerable portion of the insoluble content will be at the bottom of the vessel. It is easy then to turn out the jelly, cut off the lower portion, and with it the greater part of the impurities. It is then much easier to filter the solution after a second boiling. For the amateur worker the ordinary filter flask and laboratory filter pump will be perfectly satisfactory, and a litre can be easily filtered through hard filter paper in five minutes, even if the filter contents have to be returned to the jar for further heating. It may be as well to emphasise the point, noted by the authors, as to the necessity of keeping the solution well stirred, so as to prevent burning. The tendency to solution is very great; in fact, so much so that when once the solution has been brought to the boil it should be at once transferred to a water bath.

For commercial work the ordinary laboratory filter is far too small, but we have found that even the ordinary felt filtering bag, or rather two or three of them used in relays, are quite efficient. Naturally, however, the manufacturer would use jacketed filters and an exhaust pump. With such an arrangement the rate of filtration is but little slower than that of gelatine.

So far as can be seen at present, the future value of agar will be as a vehicle for the silver salts for papers. Far more exhaustive experiments are required to speak definitely as to its value for plate work.

The extreme thinness of the pellicle, its high melting point, and its comparatively inert nature, which somewhat recalls that of collodion, certainly point to a much more extended use in this direction. On the other hand, there are, we think, certain drawbacks, which should not be lost sight of. In the first place, using solutions of agar and gelatine of equal "thickness," the former has by no means such salt-holding powers as the latter—that is, given a somewhat heavy percentage of salts in the same bulk of solution they will show surface crystallisation much more readily with agar than with gelatine. In the second place, if, to avoid this surface crystallisation, the actual thickness or depth of the dried agar film be increased then it is extremely friable and will crack in all directions. We may also emphasise the necessity of rapid drying, not because of the liability of reduction of the silver salts, but to prevent a peculiar cracking of the film itself, which makes it hopeless for practical work. This cracking is very curious, and is seen most clearly when an agar-agar solution is coated on glass, allowed to set thoroughly, and pushed up with the finger-nail. A gelatine solution would merely hump itself together, so to say, and yet keep its homogeneous character, whereas agar seems to break into innumerable little nodules, each distinct from its neighbour. The practical effect of this would be that in commercial work, paper when being coated would have to be kept on the flat during the whole period. Not that this would be much difficulty considering the rate at which the paper dries, but it is as well to call attention to this point, for if paper coated with agar-agar be hung in fes-

toons before it is really dry this peculiar cracking will be apparent.

Messrs. Cooper and Nuttall emphasised one special advantage of this vehicle as regards papers, namely, that they can be dried at a very high temperature, and that there is therefore less "wandering"—we borrow the expressive German word—of the soluble silver salts into the support itself. There is, however, a still greater advantage in the use of agar-agar, that is connected with its lesser tendency to reduce the silver salts to the metallic state. Comparative trials, using deep narrow vessels, flat open dishes, and the ordinary emulsion pots of a factory have proved that a printing-out emulsion, with free silver nitrate, spoils under all conditions much less rapidly with agar-agar than gelatine. Unfortunately the time has not been sufficient to prove whether the same conditions hold good with coated papers, though it would seem that they would.

With regard to the use of agar for the manufacture of plates, we must confess to being not quite so hopeful. The conditions are totally different, except, of course, in the case of slow emulsions, which may be no more than the speed of bromide papers. With these there should be no difficulty. When one has to deal, however, with rapid emulsions, wherein the silver halides are so far ripened as to be practically on the verge of disassociation, then one has to be somewhat more careful. It being admitted that, in the ordinary course of manufacture, the emulsion has to be set and then broken up, washed, and remelted, the manufacturer carefully considers the after-ripening effects of these operations. What then is to be the result of raising an emulsion to boiling point? Will a fast emulsion stand such treatment?

It has been impossible, of course, in the short time since Messrs. Cooper and Nuttall read their paper to carry out a comprehensive series of experiments, but such as we have been able to make have proved most conclusively that one must re-learn much of what is now known. A fast emulsion—that is, one initially fast—will not stand the temperature of boiling water. Whether it be possible to so adjust matters that the initial speed of the emulsion shall stand such a temperature and yet turn out fast and clean (and the latter is most important) can only be proved by experiment. There is, however, one somewhat curious fact. If one takes solutions of agar-agar and gelatine of equal "thickness" and coats them on glass, allowing absolutely the same volume per area, the two behave in a totally dissimilar manner. The gelatine solution remains a coherent mass, adhering to the glass at all stages, whereas the agar-agar forms, as it were, a thin pellicle separated from the glass by a film of water. This is a very curious phenomenon, and one that we are not prepared to dogmatise on or explain. It may be, in fact, faulty manipulation on our part, but in every case where we have used agar on glass we have noticed this peculiar appearance. It is just as though the agar separated out from the water and formed a film or vehicle, distinct from the solvent. We are not prepared to say that this is going to lead to trouble, because our experiments are not complete, but in one particular application, that of colour screen-making, it is distinctly troublesome. One may prepare an agar solution of a dye and coat on glass and find that the water separates out, carrying some dye with it, causing peculiar blobby spots and stains on drying. This might be a serious matter in the case of plates, if it were, as is quite possible, the cause of frilling.

Agar-agar is, from the practical point of view, a new material for the photographic chemist and manufacturer. It promises well, and the paper printed in our last issue will be of considerable value as a starting point for the practical manufacturer.

## ETIQUETTE AMONG PROFESSIONAL PHOTOGRAPHERS.

In a recent article we raised the question of the photographer posing as the practitioner of a profession and endeavouring to place his relations with the public on a level with those of the professions generally so-called. Our conclusion was that there is very little, in fact, either to justify such an assumption or to recommend it on commercial grounds. Apart from these considerations, however, the higher status implies a propriety of conduct which we fear cannot be expected from the majority of "professional photographers" in these hard times. For while competition in the professions may be as keen as in a business, it may be held to differ from that of commercial life by its recognition of certain rules of the game. Be sharp lawyer, even a slightly shady lawyer, and you may yet preserve the respect of your colleagues, and perhaps the envy of some. But offend against some clause in the code of etiquette, and not all the King's horses and all the King's men will condone the *inconvenience* of your leg, Humpty Dumpty. Playgoers will recollect how Mr. J. A. Barrie, in "The Admirable Crichton," endows the genius of a butler with uncommon sensitiveness in "doing the right thing," a reflection, in the play, of the dignified tedious affability of his master. Our professional friend may not be one atom better or more generous than their neighbours, but they think it the correct thing to act as they were, and if we photographers are to aim at the professional code of manners we have got to take it with all its responsibilities and involutions, translated into terms of portrait photography.

It will be difficult to define precisely the acts which a photographer who desires to live up to standards of professional etiquette may or may not perform, but some which he certainly should dismiss from his programme, readily admit of definite specification. For example, to refer to a recent incident which was mentioned by a correspondent, we can scarcely imagine a photographer who claims to take a professional tone in the conduct of his business, stooping to avail himself gratuitously of the labours of another of his kind who, say, is arranging a group in a public place, and is unaware that a march is being stolen on him by the snapshot of a stealthy competitor.

Nor, to select another instance which is not infrequently brought to our notice, is it to be regarded as consistent with strictly professional conduct that a photographer should copy closely the work of some other of his colleagues (in the same town) by whom an original and novel standpoint has been selected in producing a view of some feature of the local scenery. The law of copyright, unfortunately, does not allow of his being restrained from such an action, but what can be said of the etiquette that does not prompt his abstinence from piracy in a mild form?

In matters such as these we deem the man least open to disappointment who expects the least. We fear that there will be very many ready to demur to the suggestion that, in the event of a person coming to their studios with a photograph (taken by a competitor) to be copied or enlarged, they should decline the order, and refer the customer to the photographer in whose custody the negative lies. Yet such a practice, it seems to us, is a necessary step from the principle of professional dignity.

Still fewer would be prepared to adopt the lead of a photographer in America, of whom a contemporary relates the following incident:—

"A lady with her little girl entered a studio in —, and said to the proprietor, 'I want you to make some sittings of my little girl. I was at So-and-So's studio last week, but

Although the operator made half a dozen negatives, none of them suit me; so, as I had not made any deposit, I concluded to try you.' 'Why, my dear madam, under the circumstances, I feel that you ought to go back and give that studio another chance.' They have spent their plates and their time, and really I could not be a party to such an unprofessional transaction.' After a few minutes' further conversation the lady took his advice, went back, and next time was perfectly satisfied with the proofs." The name of this hero is given—he is the vice-president of a photographers' association—but the very relation of the story

suggests the fact that such incidents are as rare in America as here, where the means by which a competitor's customers can be taken from him occupy the minds even of those who are semi-professional by general consent.

We quote these instances to give point to our contention that excellent as the professional aspiration may be, we are not quite prepared to abide by all its entails. It seems to us that the man who is content to take his photographic business as a business to be advanced by fair dealing and backed by good work is most likely to achieve success, and is most assured of respect from the public.

## DISTORTION IN SYMMETRICAL AND UNSYMMETRICAL PHOTOGRAPHIC OBJECTIVES.

[The following article, which is a shorter and more popular version of the author's previous paper in the "Zeitschrift für Instrumentenkunde," gives the curves for the distortion of a few symmetrical and unsymmetrical lenses of comparatively recent date. Since anastigmat lenses of both types are issued by almost every lens maker at the present time, the proofs which Dr. Wandersleb's laborious measurements supply of the fact that distortion is not an inherent property of either symmetry or non-symmetry are of real practical interest to the photographer. The text of the previous paper shows that there are lenses which give distortion in a higher degree than those here selected, and that the majority of those giving a greater distortion are of the unsymmetrical type. The examples now given by Dr. Wandersleb are evidently selected to show that when comparing modern lenses of high quality the fact of symmetry is not a guarantee of absolute freedom from distortion at various scales of reproduction, and that a non-symmetrical type may in fact compare favourably with one symmetrical in its construction.—Eds. "B.J."]

AMONGST photographers it is almost generally accepted that lenses, the elements of which are symmetrical with respect to the diaphragm, are, on account of this symmetry, free from distortion; and that, on the other hand, unsymmetrical objectives are inherently possessed of this defect. As an illustration of this article of faith the following excerpt from a German book on the photographic objective, recently published and enjoying a fairly large circulation, may be quoted:—

"Whilst in symmetrically constructed doublets, that is to say, in the anastigmats (for instance, the Goerz double anastigmat), the aplanats, and the periscopic lenses, distortion is strictly excluded, we find the defect prevailing in single lenses, also in doublets of the unsymmetrical type (some anastigmats, portrait lenses, etc.). The defect is certainly not so pronounced as in the single lenses, but nevertheless it does exist, and manifests itself in such a manner, that unsymmetricals cannot be recommended for photography in which correct drawing is a desideratum, as, for example, in architectural work."

Other books on photographic optics, and especially the prospectuses of some optical firms, perpetuate this idea.

That this dogma is directly opposed to actual fact was known, published, and demonstrated in England forty years ago. Ten years ago the subject was again discussed, and thoroughly treated from the theoretical standpoint.<sup>1</sup> That this dogma has so stubbornly maintained its hold up to the present time—the above notwithstanding—may be due to the fact that curves, such as have been in the last few years widely used and have contributed much to a clearer understanding in regard to the other image aberrations of the photographic lens, are as yet apparently unknown for illustrating distortion of the image. The writer has therefore, in an exhaustive article,<sup>2</sup> undertaken the task of publishing such curves for a large series of well-known objective types, and in connection therewith of giving a résumé of previous literature on the subject. In the following only one or two points are briefly discussed.

The error of distortion in a photographic lens consists in

reproducing objects, which extend towards the margin of the field of view relatively to those lying in the middle, either too small or too large, and in most cases in a higher degree the further the objects extend from the middle of the field towards its margin—that is to say, the greater the angle of the field of view. In the case of too small reproduction of the outlying regions, straight lines—for example, the lines of a house—appear bulged outwards in the margin of the field of view; in the other case they are curved inwards. From this fact, the first kind, which is particularly noticeable in landscape lenses with the diaphragm in front, is called "barrel" distortion; the second kind, which is found in a high degree in many tele-objectives, "pin-cushion" distortion.

It is not permissible to speak of the "freedom from distortion" positively, i.e., for all ranges. Distortion can be eliminated, strictly speaking, only for a definite object distance, that is to say, for a definite scale of reproduction,  $N$ . Being once corrected for  $N$ , other scales of reproduction exhibit traces of secondary distortion, and generally to a greater degree the greater the relative attainable aperture of the objective. In objectives with the large relative aperture  $f/4.5$ , the alteration in the error of distortion is, in general, greater with the scale of reproduction than in an objective whose maximum relative aperture is only  $f/18$ . If, however, the larger aperture be stopped down to  $f/18$ , the inherent distortion is, of course, by no means removed.

Symmetrical objectives occupy a peculiar position, in so far as in them, without any assistance on the part of the constructor, freedom from distortion for reproduction in full size is always to be obtained, but the largest errors of distortion for the reproduction of distant objects still exist. In unsymmetricals, on the other hand, the constructor in many cases purposely seeks out that scale of reproduction—for example,  $N = \infty$ , or  $N = 10$ —for which he wishes to eliminate distortion to the greatest possible degree.

Respecting the particular scale ( $N$ ) for which distortion should be corrected, in landscape work  $N$  is very large ( $N = \infty$ ), in architecture and instantaneous exposures of the most varied kind  $N$  usually lies between 300 and 10. In interiors and portraits  $N$  is frequently equal to 10 or there-

abouts. A smaller than 10 is the exception in amateur photography, as that would mean that objects lying nearer than about  $1\frac{1}{2}$  yards were being taken with a quarter-plate camera whose objective has a focal length of about 6 in. For this reason, in the following curves, the error for distortion is given for the two extreme values,  $N=10$  and  $N=\infty$ .

The distance of the curves from the horizontal straight lines gives at once the difference pro thousand between the actual

is remarkably exemplified in Figs. 1 to 10.<sup>3</sup> The symmetrical universal objectives here reproduced are in by far their greater range of application by no means free from this error, and unmistakably show "pincushion" distortion, whilst the notable unsymmetrical doublets given along with them are for the same range almost perfectly free from distortion.

As to the effect of the deviations here represented, practical evidence can easily be obtained, if one of the well-known rapid

size of image and the exact size of image for the half-angle of the field of view, which can be read off on the horizontal.

It will be at once conceded that there are unsymmetricals extant which show very much greater errors of distortion than symmetricals. But it must also be said that there are unsymmetrical objectives in which, for the most important cases, distortion is eliminated to a very much more perfect degree than is possible in symmetrical objectives of the like rapidity. This fact, though contradictory to the views in current belief,

symmetrical objectives be chosen for investigation and employed up to the large field of 80 deg., or even 90 deg., frequently claimed for lenses of this type. It should be arranged so that the margin of the field of view contains a straight line, and then it will be seen that a very determined curvature in this line towards the middle of the field is the result.

DR. E. WANDERSLEB.

<sup>3</sup> E. Wandersleb, "Zeitschrift für Instr.-Kunde," vol. 27, p. 33, 1907. See also p. 145, Eder's "Jahrbuch für 1907," from which the following ten figs. are taken.

**COPYRIGHT IN PAINTINGS.**—A decision of great importance regarding the protection of copyright in paintings in the United States has (writes a correspondent to the "Times") just been arrived at by the Supreme Court at Washington, and ends a lawsuit which has for a number of years been carried on by the Berlin Photographic Company (of Berlin, London, New York, and Paris) against the American Tobacco Company and the American Lithograph Company, who had reproduced Dendy Sadler's well-known picture "Chorus," of which the Berlin Company held the copyright. The offenders were aware that the copyright belonged to the Berlin Photographic Company, but they insisted that it had no value in the United States (although it was duly entered at Washington), because the original painting, when exhibited at the Royal Academy in London, did not bear an inscription to the effect that the copyright belonged to anyone. They further claimed that, according to

American views, the exhibition in a public gallery made a picture public property. The case was brought up through the various stages of the courts, until the Supreme Court of the United States decided in favour of the rightful owners of the copyright, and declared that the public exhibition of a painting does not amount to a publication within the meaning of the statute, and that the copyright notice which has to appear on the reproductions need not be on the original painting.

**HACKNEY PHOTOGRAPHIC SOCIETY.**—The annual concert will be held on February 4 in the Board-room, Hackney Baths, when the chair will be occupied by the president (Mr. A. J. Linford). In addition to an interesting programme of both vocal and instrumental music, a musical farce, entitled "The Man in Possession," by Mr. Harold W. Lane, will be produced under the direction of Mr. A. Cook.

## A PHOTOGRAPHER'S SCHEME FOR BEAUTIFYING LONDON.

We have referred on previous occasions to the plan suggested by Mr. F. W. Speaight in 1905 for the improvement of the surroundings of the Marble Arch. The scheme has already been endorsed by the City of Westminster and the Boroughs of Paddington and Marylebone, each of which bodies have voted a sum of £2,112 towards the cost, whilst the City of Westminster has in addition agreed to maintain the increased

we may quote the "Times" of Friday last, in which it is stated that "if it be adopted and carried into effect the position of the Marble Arch in relation to Hyde Park will be different from that which it occupies to-day. The arch will remain on its present site, but a part of the park immediately to the rear of it will be thrown into the public highway, and the result will be that traffic at this congested point will be

roadways at an estimated cost of £600 a year. To embark on any public work, however, in London, is to reckon with the London County Council, but it is satisfactory to record that at its meeting last week the Council received a recommendation from its Improvements Committee that a scheme differing very little from Mr. Speaight's original suggestion should be adopted, as will be seen from the reproduction of Mr. Speaight's original drawing. As showing the interest taken in the scheme,

able to pass behind the arch, instead of, as now, only in front of it. As far as one can judge from the plans, a great public improvement will result from the carrying out of the scheme, and the part which a private citizen has taken in advocating it should not be allowed to pass without acknowledgment."

As we go to press we read that the London County Council has adopted the scheme and expressed its obligation to Mr. Speaight for its origination.

## ORTHOCHROMATISM BY BATHING.—A SENSITOMETRIC STUDY.

[THE following is the full text of a further communication in the appearing as "Studies in Sensitometry." The same author's first last year, and were reprinted in our columns from proofs specially prepared, as was the present paper, by Mr. Wallace, for "The British Journal of Photography." Our acknowledgments are therefore equally due to Mr. Wallace and to the "Astrophysical Journal," in which the papers have first appeared.—EDS., "B.J."]

### Object.

In a previous paper<sup>1</sup> the writer has referred to the evaluation of colour-sensitiveness in photographic plates, and has suggested a method for the production of spectrum negatives directly comparable with one another. This second paper deals further with this subject.

The main object of the present work was the investigation of orthochromatic action by bathing-methods, and the means of producing maximum effect throughout the entire visible spectrum with the

series of researches by Mr. R. J. Wallace, of the Yerkes Observatory, published experiments on a system of daylight sensitometry appeared prepared, as was the present paper, by Mr. Wallace, for "The British Journal of Photography." Our acknowledgments are therefore equally due to Mr. Wallace and to the "Astrophysical Journal," in

dyes now at the disposal of the worker in photography. Not only was it desired that the plate be "panchromatic," but it was also sought to be as truly isochromatic as possible; that is to say, equality of deposit for the various regions throughout the spectrum was considered as of primary importance, provided that it was not obtained at too great a sacrifice of speed. This latter consideration therefore eliminates the introduction of any dyestuff whose function would simply be a screening action upon the plate.

Throughout the course of the work certain combinations presenting more than common interest were noted and investigated as they

<sup>1</sup> *Astrophysical Journal*, 25, 116, 1907.

occurred. In no case was any effort made to record a sensitiveness which required an abnormal exposure when compared with that necessary to obtain full printing density in the blue-violet.<sup>2</sup>

### Method of Work.

The sensitizing influence of the cyanines and isocyanines upon gelatine dry plates has been the subject of investigation by a very large number of workers, principal among whom may be mentioned Eder and Valenta, von Häbl, Stenger, König, Mees and Sheppard, etc., and much has already been published. The work, however, does not appear to have been sufficiently extended, and it has therefore seemed good to the writer that with a chosen set of dye-stuffs all possible combinations should be experimented upon, and under variations sufficiently great to render the work comprehensive.

The dyes selected were assigned numbers and divided into groups, the first of which was arranged as follows:—

1. Pinacyanol,
2. Pinaverdol,
3. Pinachrome,
4. Homocol,
5. Dicyanine.

With these five numbers as a base the following combinations were made:—

- 1, 12, 13, 14, 15, 123, 124, 125, 134, 135, 145, 1234, 1345, 12345,
- 2, 23, 24, 25, 234, 235, 245, 2345,
- 3, 34, 35, 345,
- 4, 45,
- 5,

which represent all possible combinations with five figures.

The composition of the preliminary (or "first test") bath was

Dyestuff (1:1000 sol. in alcohol) .....	2-7 cc.
Water .....	200 cc.
Ammonia .....	3 cc.

the variable amount of dye solution depending upon the number of components. All plates from this bath were bathed and dried without supplementary washing.

The type of plate selected for bathing was the Seed 27 "Gilt Edge," and the length of bathing was in every case three minutes.

Each of these plates (size  $3\frac{1}{4} \times 4\frac{1}{4}$  inches) was then exposed to a series of diffused daylight spectra, in the "standard" spectrograph for 15 and 30 seconds, and 1, 2, 4, 8, 12, 16 minutes respectively; two supplementary exposures were also made, first, through an aesculin filter absorbing all wave-lengths shorter than  $\lambda$  3968, the object being the avoidance of false conclusions in sensitiveness due to the overlapping of the second order ultra-violet. The second exposure was made through an ammonium picrate filter, whose absorption ended rather abruptly at  $\lambda$  5200, and with the collimator wedge in position, which displaced the spectrum relatively along the plate, thus bringing the B line about equally distant from the two edges. This latter exposure is of great value in determining extent of practical sensitiveness.

From the set of thirty-one "type-plates" thus secured (each con-

<sup>2</sup> A note may be interpolated here upon the fallacious results obtained with bright-line, discontinuous spectra in the estimation of chromatic sensitiveness. It is possibly as true as it is practical that if a plate can be impressed with a radiation of certain wave-length, it is then "sensitive to" such radiation; but it is well known that plates may be "forced" in exposure, or (what amounts to the same

thing) the intensity of the radiation may be so increased that a sensitiveness is recorded in a region to which the plate is, in the narrower but more practical meaning of the word, entirely insensitive. As such an example the illustration appended needs no comment.

For description of this instrument see former paper, previously referred to.

taining nine spectra) twenty were selected for continued study possessing particular interest, and with these the treatment varied according to Table I.

The assignment of decimals was simply to facilitate the recording of results in the laboratory note-book. For example, type 14 then represents a "27" plate bathed in pinacyanol+homocol, in bath composed of water+alcohol+ammonia, and washed in alcohol; the subscript *e* refers to temperature and will be considered presently.

TABLE I.

Basic Constitution of Dye Bath.	Subsequent Washing.
0.1 Water .....	No washing
0.2 Alcohol .....	No washing
0.3 Water + Alcohol .....	No washing
0.4 Water + Ammonia .....	No washing
0.5 Alcohol + Ammonia .....	No washing
0.6 Water + Alcohol + Ammonia .....	No washing
0.7 Water .....	Water
0.8 Water + Alcohol .....	Dil. alcohol
0.9 Water + Alcohol .....	Alcohol
0.10 Water + Ammonia .....	Water
0.11 Water + Alcohol + Ammonia .....	Alcohol
0.12 Water + Alcohol + Ammonia .....	Dil. alcohol
0.13 Water + Alcohol + Ammonia .....	Water
0.14 Water + Ammonia .....	Alcohol

Upon examination, this large number of plates was capable of furnishing very authoritative information upon certain combinations which were therefore isolated and subjected to further study by varying the amount of dye in the component parts of the combination.

The influence of temperature of the bathing-solution and washing bath was also investigated at temperatures ranging from 12 deg. to 30 deg. C., at which latter point the gelatine film partially dissolved, the series of subscript letters already referred to indicating the temperatures.

<i>a</i> = 12° C.	<i>b</i> = 15
<i>c</i> = 18	<i>d</i> = 20
<i>e</i> = 23	<i>f</i> = 24
<i>g</i> = 26	<i>h</i> = 30

A second group of dyestuffs, consisting of

6. Orthochrome I.,
7. Cyanin,
8. Ethyl Violet,
9. Tetraiodofluorescein,
10. Ethyl Cyanin T.,

was handled in a similar but less extensive manner to Group 1 (twenty plates being made), and deductions from the spectra obtained thereon allowed of a further reduction to ten, as showing probable interest in combination with the secondary and final selections of Group 1. These combinations were in turn made up, plates again bathed, and the spectrum photographed.

Besides the dyestuffs arranged in the two groups already referred to, a large number of others<sup>4</sup> were also experimented with in combination with those contained in Groups 1 and 2, but only such as present interest in connection with the main object of the present investigation.

Fig. 1.

tions are referred to throughout the succeeding portion of this paper. It may be stated, however, that the total number of plates exposed numbered 287, besides 40 for acetylene duplication and speed determination, aggregating over 2,500 separate exposures.

<sup>4</sup> Among the remaining dyes experimented with during the course of the present work may be mentioned Pinachrome Blue, Echt Rot, Rose des Alpes, Fluorescein (Monobromo-, Diiodo-, Tetrabromo-), Glycin Red, Acridin Yellow, Chinoline Red, Benzo Green, etc.

### Drying-Cabinet.

The bathing of all plates was conducted in total darkness (time kept by means of an indicating metronome), and dried in a cabinet constructed especially for that purpose, and which may now briefly be described. Reference to the drawing will make the description sufficiently plain.

ABCD (Fig. 1) is a box closed in front by a light-tight door E, and containing two racks FF', in which were stood the plates to be dried. A constant current of air, supplied by an electric fan at G, was driven through the rectangular elbow-tube H, and entered the box proper at K, passed between and over the plates at FF', and thence through M to the outer air. A skeleton coil of German silver resistance wire at N was supplied with current, and by this means the incoming air was heated and dried. In use the fan was boxed in by a rectangular wooden frame, covered with muslin, which in practice served well to eliminate any trouble due to dust. The resistance coil was so wound that the heat generated in the drying-box averaged 32 deg. C., after running for 30 minutes.<sup>5</sup> Separate switches for the fan and coil enable either to be "cut in" independently.<sup>6</sup>

### Check-Plates and Speed.

Examination of the final plates as to fitness for measurement also indicated the most interesting types, and of all plates thus selected their corresponding dye baths were again made up and a new series of plates bathed therein under precisely similar conditions as recorded with the former set. These plates were then cut a half; one section was exposed to the spectrum of a constant acetylene flame for a series of exposures of 1, 2, and 3 minutes, while the spectrum of diffused daylight was impressed for 2 and 4 minutes at the top and bottom. The daylight spectra in this duplicate set served for two purposes: (1) as position indicators by means of the Fraunhofer lines, and (2) as a check upon the plates already noted in the first series. The acetylene flame spectrum simply served to show that the plates were relatively as noted, but cannot, of course, serve for measurement except between themselves, on account of the difference in chromatic intensity between its light and daylight.

The remaining section of the plate was exposed to daylight in the rotating sector machine,<sup>7</sup> together with an unbathed "27" plate of the same emulsion number, and they were developed together. From this exposure was extracted the relative speed. In practice three bathed strips and one "27" were exposed and developed simultaneously.

After checking up the daylight plates with their corresponding acetylene plates, the former were measured in the spectra-photometer and their densities plotted as ordinates against wave-lengths as abscissæ, selecting that spectrum exposure on each plate which corresponded to an approximate density of 2.5 in the blue-violet.

As has been stated, it is not intended to detail the results from all of the plates thus obtained, but instead, reference will be made to but two classes—viz., those which possess primary importance because of sensitiveness throughout the entire spectrum, and those which are important by reason of special sensitiveness for a limited spectral region. In both instances the relative sensitiveness-ratios are tabulated for as many positions as may be necessary to convey truthful impression of the results, while particular cases are subject to more complete measurement and graphically illustrated by their accompanying curves.

### Evaluation of $\chi$ .

It must be pointed out that, while, at first sight, the value for  $\chi$  has been recorded in apparently the same manner as pursued by Mees and Sheppard—viz.,  $\frac{\text{blue-sensitiveness}}{\text{yellow-sensitiveness}}$ ,<sup>8</sup> yet the value is arrived at in a somewhat different way, for while these workers obtain it as  $\frac{\text{yellow-inertia}}{\text{blue-inertia}} = \frac{\text{blue-sensitiveness}}{\text{yellow-(or red) sensitiveness}}$ , the value

<sup>5</sup> The wire used was B. and S. gauge No. 34, and the amount was approximately 20 ft.; the current was 110 volts, direct.

<sup>6</sup> The importance of rapid drying of bathed plates has been pointed out by von Hübl (*Das Atelier*, 1906, p. 6) and also by E. Valenta (*Photo. Korr.*, September 1907; also *Brit. Jour. Phot.*, 54, 751, 1907). The drying-cabinet in use by the writer was constructed in July 1903, and has been in use since with unvarying success.

<sup>7</sup> See Studies in Sensitometry. I., by the author. "B.J." May 17, 24, and 31, and June 7, 1907.

<sup>8</sup> First advanced by Eder, *Beiträge zur Photochemie*, III. Theil. 126; also *Système de Sensitométrie*, p. 133.

of such inertia having been obtained behind broad-banded filters, the present  $\chi$  value is obtained from the ratio of the densities measured directly from the spectrum plate, and hence, relatively speaking, replaces qualitative values by quantitative. Thus, in the present instance,

$$\chi = \frac{\text{density of blue at } \lambda \text{ 4100 } (= \beta)}{\text{density of } \lambda_n}$$

It will therefore be noted that the lower the value of  $\chi$  the higher the chromatic sensitiveness.

The shift in sensitiveness towards the red from the point of maximum absorption of the dye, following Kundt's law,<sup>9</sup> and due to the high refractive index of the silver salts, has already been noted and commented upon by many writers; also, in view of the fact that the absorption of these later dyestuffs is very definitely known, the inclusion of further work upon this point has not been considered necessary.

### Nature of Plate Used for Bathing.

It is often a point when emphasised that there should be selected for bathing a plate which is originally "fog free," and several writers have advocated the use of slow plates as being conducive to the best results. In the course of the present work there were included Seed and Cramer lantern-slide plates. Seed "26x," Seed "23," Seed "process," and Cramer "Crown," besides special instances where use was made of Cramer "Instantaneous isochromatic" and Cramer "Trichromatic." The results from these plates, coupled with experience gained in plate-bathing and covering a period of fourteen years, lead me unhesitatingly to the rejection of slow plates as being wholly unsuited to the end in view.

It goes without question that initially the plate selected must be free from fog, but after the best possible effect has been obtained—i.e., the lowest value for  $\frac{\beta}{\lambda_{\text{RED}}}$ , it still follows that the point of maximum sensitiveness of any plate, due to the silver salts, will not be materially shifted from its original position unless (1) the dye taken up by the silver bromide and gelatine be in such amount that it exercises a selective screening effect upon the light incident upon its surface, or (2) by the introduction of some dye which (otherwise inert) is present solely for the purpose of acting as a colour-filter.<sup>10</sup>

Eliminating from the discussion this latter phase,<sup>11</sup> and considering the former modified by the fact that the amount of active dye introduced is limited by reason of its negative sensitising effect when in excess, we find the question considerably narrowed. It follows, then, that not only must the plate be free from fog, but it must also be so chosen that its development-factor for blue-violet light ( $\gamma\infty\beta$ ) be as low as possible; by this means we are enabled to attain the maximum of development action without excessive density in the blue-violet, and hence a more uniform action throughout the spectrum.

### Development.

In but little of the work hitherto published is any mention made of the adoption of precautionary measures to insure the constant value of the factors controlling development. It is known that variation in development-time, temperature, or constitution will undoubtedly affect the values of the spectrum-curve, so that unless these constants be kept very rigorously exact, the value of the result will be vitiated to a greater or less extent depending upon the amount of variance. Throughout this work, therefore, the development of all plates was kept constant in constitution of developer and time of development, while the use of a water-bath of 70 litres capacity fitted with electric control assured steady temperature. The development tank is of thin glass, rectangular in shape, and all plates were handled and developed in total darkness.

Some consideration may now be given to the correct duration of development. It will be obvious that if any plate which possesses a high  $\gamma\infty$  for the blue-violet region receives the minimum of exposure, it may, by continued development, be made to give the required density in that region without showing the true relative colour-effect. On the other hand, the same plate may be exposed

<sup>9</sup> A. Kundt, "Ueber den Einfluss des Lösungsmittels auf die Absorptionsspectra gelöster absorbirender Medien," *Annalen der Physik*, 4, 53, 1878. See also Eder and Valenta, *Beiträge zur Photochemie*, III, 85.

<sup>10</sup> E. König, "Non-screen Orthochromatic Plates by Bathing," *Brit. Jour. Phot.*, 54, 736, 1907.

<sup>11</sup> Plates for astronomical and general scientific use must be of as high a speed as possible, whence it is impractical (from this standpoint) to consider the presence of a "screening" dye, as its action "slows" the plate.

until the blue-violet region has reached the over-exposed portion of the characteristic gradation-curve, and yet from development with a weak reducer, or from lack of sufficient length of development-time, it may in its densest part record a value even lower than the 2.5 necessary. Both plates would be equally untrue when considered as a record of relative sensitiveness.<sup>12</sup>

Hurter and Driffeld have shown<sup>13</sup> that in the gradation-curve of a photographic negative the true relation of the original light-values is obtained only when the development factor ( $\gamma$ ) of the negative equals 1.0. If lower than 1.0 then the tonal values will be reproduced with too small a difference between them, while if greater than 1.0 then the differences will be exaggerated. At the same time it must not be lost sight of that the production of a negative is not the final stage in the photographic process, but merely the means to an end, which "end" is a positive proof whether it be on glass or paper. It is also a well-recognised fact that different positive processes require a different type of negative, i.e., more or less "contrasty," or, correctly speaking, of different  $\gamma$  value.

The greater the amount of development action (within limits) which a well-exposed plate receives, the higher becomes the value of the  $\gamma$ . In the recording of scientific data development is often forced in the endeavour to bring out faint detail which lies beyond the period of the straight portion of the characteristic curve, and is located in the region of under-exposure, with the result that the more exposed portions of the plate become abnormally dense, and are generally subject to a later local reduction. In sensitometric tests, however, it is obvious that development should not be continued beyond the point where it is possible to reproduce the scale of values in its entirety.

It would appear, therefore, if  $\gamma_{1.0}$  means that throughout the "straight" portion of the plate curve, the deposits are proportional to the logarithm of the light received, that such a value would be correct for the development of the spectrum exposures. Theoretically, the simplicity of such a solution is marred by the fact that it has been shown that the gradation-curve varies slightly with the wave-length of the light; so that it results from this that if  $\gamma = 1.0$  at, say, the blue region, then in the yellow the value may be, say,  $\gamma_{1.1}$ <sup>14</sup>. In practice, however, the objection may be dismissed, as the variance involved is exceedingly small, and in work of this nature, when handled in the method proposed, becomes a vanishing quantity.

The great number of positive printing-media now available are called forth principally by the necessity of supplying the general worker with a means of obtaining presentable results from negatives which, from many reasons, have been improperly exposed or developed. In sensitometric work uncertainty of exposure and development has been eliminated, so that it simply remains to consider the process best suited for use. Such process is unquestionably that of a positive upon glass, and, therefore, the  $\gamma$  value of the negative must be altered to suit the capacity of the process, the amount and direction of such alteration depending upon the medium selected.

Taking only two examples from many media, let us consider development paper, on the one hand, and a transparent positive on glass on the other.

Three sector-disc negatives were taken which had been developed for different times and had measured development-factor values of  $\gamma_{0.8}$ ,  $\gamma_{1.2}$ , and  $\gamma_{2.5}$  respectively. All three were printed simultaneously on "portrait velox" for 4, 6, 10, and 16 seconds, exposure being to a constant light-source. All four prints were then developed in rodinol.

Examination showed that it was possible to reproduce only one of the negatives so that all of the tones would show, viz.,  $\gamma_{0.87}$ , the remaining two being too "contrasty," so that in printing for the tones involved in the higher densities, the other end of the scale

was lost. A transparency, however, on a Seed "27" plate gave complete scale of tones up to about 5.0 H. and D. units ( $\gamma_{2.5}$ ).

Now, if it be possible to print from a negative showing all tones between 0 and 5.0 it should (theoretically) be practical simply to develop the plate containing the series of spectrum exposures at temperature and for the time necessary to reach a development factor value of approximately 2.5. Objection to this course lies in the fact that although it is possible to measure in the neighbourhood of this density, yet there is in the hands of the writer an unreliable attendant upon such measures, and they are rendered possible only by the introduction of a supplementary measured density plate to the polarised beam. For convenience, therefore, and as being conducive to more reliable results, direct measurements are not made upon a density of higher value than approximately 2.5. Inasmuch as the slope of the gradation curve is dependent principally upon the amount of development action, it suffices, then, that the spectrum plate be developed with the same developer, for the same length of time, and at the same temperature, as the sector-disc plate of same constitution, which when measured records a value  $\gamma_{1.2}$ . This method, although not absolutely exact, is sufficiently near truth to be accepted, when we take into consideration the accidental errors of the evaluation. By exposure of a plate of similar nature through narrow-banded filters it would be possible to obtain sensitiveness values for various limited regions, which, with reference to the blue sensitiveness, could be easily calculated into a measure  $\gamma_n$  for use with the spectrum plate; but such a method would be refinement possessing no truly practical value, and would require to be redetermined for every variation in the sensitising bath.

It may be stated that a Seed "27" plate exposed to daylight the sector-disc machine requires three minutes' development at temperature of 20deg. C., with a solution of rodinol 1 : 24, in order to attain  $\gamma_{1.2}$ .

ROBERT JAMES WALLACE.

(To be continued.)

#### DEATH OF H. S. MENDELSSOHN.

WE regret to have to announce the death of Mr. Hayman Samuel Mendelssohn, which occurred on Friday evening last almost suddenly.

Mr. Mendelssohn was born in Germany, but his youth was spent in Poland. In his early manhood political reasons obliged him to leave that country, and he settled at Newcastle-on-Tyne, where he commenced his photographic career. After serving with Mr. L. Downey for some time, he went into business for himself, and was so successful that he found it advisable to take advantage of the wider scope for ability that London affords, and removed his business there about twenty years ago. In a brief space of time he established a reputation which has stood until the present time.

Mr. Mendelssohn joined the Royal Photographic Society in 1884 and was an original member of the Professional Photographers' Association. In the management of the latter organisation he took an active part, and was a regular attendant at the meetings of the committee. The suddenness of his death necessitated a coroner's inquest, which was held on Tuesday morning, and the funeral took place on the same afternoon at the Jewish Cemetery, Willesden Green.

**THEFT OF MINIATURES.**—A burglary took place last week at Messrs. Carl Hentschel's colour works at Knight's Hill, West Norwood, the burglars succeeding in effecting an entrance from the rear through some private grounds belonging to Portobello House. After generally ransacking the place and taking away a large number of tools, they succeeded in opening a safe and abstracting three miniatures in gold frames of the daughters of the Queen, painted on ivory and believed to be the property of the Queen. They were being reproduced for Mr. Turrell for a book on miniatures. Mr. Carl Hentschel, in conjunction with Scotland Yard, has left no stone unturned to recover the valuables, and it is satisfactory to record that on Monday last they were traced, through the good services of a publican at Brixton, to whom they were offered for sale.

<sup>12</sup> J. Precht and E. Stenger, "Die Farbenwerte auf panchromatischen Platten in ihrer Abhängigkeit von der Entwicklungsdauer," *Zeitschrift für wissenschaftliche Photographie*, 3, 67, 1905.

<sup>13</sup> *Jour. Soc. Chem. Indust.*, May 31, 1900.

<sup>14</sup> Mees and Sheppard, in their *Investigations on the Theory of the Photographic Process* (Longmans, Green & Co., 1907), p. 307, arrive at the conclusion that  $\gamma$  remains unaltered by different wave-lengths, the alteration existing merely in the shape of the curve, and due principally to differences in the optical opacity of the film, resulting from different coloured lights. See also article by E. Stenger, *Zeit. für Reproduktionstechnik*, March, 1906.

<sup>15</sup> The value of 5.0 was obtained by extrapolation, this density being too high for measurement without the use of special methods.

## Exhibitions.

### PHOTOGRAPHS AND MULTIPLE MOUNTING BY MR. FREDERICK H. EVANS.

At the rooms of the Royal Photographic Society Mr. Frederick H. Evans displays an interesting collection of his works, particularly with a view to demonstrating the advantages of the American manner of mounting photographs. The admirers and friends of Mr. Evans will not find here anything new, as most of the works are well known through exhibition and reproduction, and his mounting is not different in style from the usual thing expected of him. But where the advantage of this exhibition lies is in the object-lessons afforded by several duplicate prints mounted in alternative schemes of tint. Those who have not accustomed themselves to the observation of these matters will find it difficult to believe that a bright and shining print gleaming like a jewel in the centre of a mass of dark-toned mounts is an identical replica of another set in a pale scheme, where it looks rich, full, and sombre. Take, for instance, the delightful long-shaped "Beaucaire." In the one case its walls and turrets shine out with a strong effect of sunlight. Its sky is full of light; its river is grey. In the other case it seems to be frowning in a sullen gloom and backed by a sultry, heavy sky, with the river running darkly before it. The former print is trimmed an inch shorter, that is really all the difference between them actually. The dark one has an inch and a quarter of delicate dove-grey border with two white lines, and beyond that an expanse of French grey mount. The gleaming print, on the other hand, has at top an inch, and at bottom two, of a heavy purple-grey and two lighter lines far apart, and beyond this a wide margin of a contrasting dark grey a little less deep in tone. These two examples are taken as typical of many, and of the general principle of mounting in various tints. It is not claimed that the one is any better than the other. A choice is very hard to make.

But it is not only in the matter of tone that these qualifying factors exist. Pattern also takes a part. It may be noticed with what very subtle feeling the shaft and capital in No. 11 is bordered by two pairs of lines (black and grey), separated by the greeny white of the mount. The result is very lively and piquant, and carries out exactly the idea of the subject where the sharp chiselling of the fluting of the shaft and the carving of the capital takes strong relief and contrast from the falling of the light upon them.

As a general principle, however, contrast and complementaries in tone and colour are more relied upon than pattern and proportion in the various superimposed papers. This principle is regulated by taste, and in Mr. Evans's case the designing of his mounts and the adoption of their somewhat quaint, but never-erring shapes, is very obviously the outcome of a mind brought up upon *objets d'art et vertu*. His mind is, indeed, almost Japanese in its workings. His art is precise and exacting; the antithesis of that sort which looks broadly and swiftly and cries: "That's near enough; what's it matter?" Those who have been privileged to see him in his workshop know that his art is patiently painstaking and relentless.

If mounts and frames are to be perfected at all they can only be perfected in this way, and there can be no better education for one wishing to acquire refinement in this matter than to study quietly the mounts here shown and their effect upon the prints they embellish.

The American method, as it used to be called, of laying one colour of mount over another until each and all temper and qualify mutually and the mass sets off the print to the greatest possible advantage, is a method that few have the time or the means to indulge in freely. But those who are so fortunate know its inexhaustible resources. A deeply-shaded aisle in a cathedral is wanted to be as impressive as possible: mount it in a pale grey and it is forcible. Does it lack atmosphere? Then put a band of deeper, warmer colour near it and it is to the eye at once behind a thin veil of grey. Is it too hot in tone? Make the mount richer in warmth and it becomes pearly. A picture of sand dunes here blazes with sunshine which is forced from it by the low and retiring tone of the mount. And so on throughout all the examples, which comprise landscapes and portraits, as well as architectural subjects.

F. C. TILNEY.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents were received between January 13 and January 18:—

**PROJECTION APPARATUS.**—No. 779. Improvements in projection apparatus. Robert Alfred Ives and Alfred Wrench. 21, Melgund Road, Highbury, London.

**VIEWING APPARATUS.**—No. 825. Improvements in or relating to apparatus for viewing stereoscopic or other pictures. Jules Richard, 53, Chancery Lane, London.

**PIGMENT PROCESS.**—No. 1,027. Improvements in pigment photographic processes. George Ernest Gibson, 20, George Square, Edinburgh.

**PHOTO-TELEGRAPHY.**—No. 1,203. Improvements in connection with the telegraphic transmission of photographs. Frank Wyndham, 11, Grosvenor Road, Norwich.

**PHOTO-TELEGRAPHY.**—No. 1,209. Transmission and reproduction of pictorial representations by electrical agency. John Joseph Pearson, 10, Jamaica Road, Bermondsey, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**CHANGING-BOXES (DAYLIGHT LOADING).**—No. 13,957. 1907. The invention relates to changing-boxes for the daylight loading and unloading of photographic plates, comprising two receptacles, movable or removably secured to each other, and to magazine-boxes, to be used in conjunction therewith.

According to one construction, as hitherto proposed, the two receptacles are temporarily hinged to each other, and their adjoining walls are provided with slots for permitting the exposed plates to slide from one receptacle into the other, the slots being under the control of slides and the plates to be exposed being pressed forward by a spring. According to another construction, the two receptacles fit into each other, and the inner one receives a magazine-box to the end cover of which is attached a frame supporting the plates to be exposed, the arrangement being such that, before each exposure of a plate the inner receptacle is drawn out together with the magazine-box, and with the plates which have already been exposed, the whole magazine-box being capable of being withdrawn with the plates, which have been exposed and those which might have been left unexposed.

The present invention consists in wrapping the cartridge of plates in an opaque envelope-shaped wrapper adapted to receive the plates after they have been exposed, and in adapting a change-box to be used in conjunction therewith.

The invention also consists in the improved means for the daylight loading and unloading of photographic sensitised plates.

Each plate has, as usual, an anti-halation or other backing provided with slightly thickened portions or raised strips along two edges of the plate parallel with its line of travel to prevent the sensitised face being scratched or rubbed. This backing may be completely gummed or pasted on the plate, or attached either at one or both ends, so as to be easily removed when developing.

The plates are packed with their sensitised faces foremost in an opaque cartridge, and the number of plates and size of the cartridge corresponds with the capacity of the plate-holder.

The cartridge consists of a shallow box of wood, metal, cardboard, or other suitable material, formed with a longitudinal slot or opening in its back, whilst upon the front edges of three of its sides are formed undercut guides, adapted to receive the side edges and one end of an opaque detachable flexible cover, formed on or as an extension of the cartridge, and passing in front of the sensitised face of the foremost plate, around the outlet end of the cartridge and thence around the back thereof, where its end is secured, or the whole cartridge held intact by a band.

This cartridge is placed in an opaque enveloped-shaped wrapper, open at one end only, and one side of the wrapper is preferably

longer than the other, and is gummed on its interior edge. The package of plates made up in the manner above described is then in its marketable condition. For details of the changing mechanism the drawings in the original specification require to be consulted. Rupert Richard Allen, "Rubra," Hotham Street, East Melbourne, Australia.

**DEVELOPERS.**—A German patent has been granted to Dr. Meuter, of Vienna, for a photographic developer containing an amide of the mono-, di-, and trioxybenzoic acids and their monohalide substitution products. Gallamide or the amide of trioxybenzoic acid is the best. This is made by boiling tannin with acid ammonium sulphate and ammonia. The gallamide is mixed with a 3 or 4 per cent. solution of potassium metabisulphite and sufficient caustic potash solution added to form a perfect solution and the phenolate. For use this is diluted with 20 parts of water.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Pigment for the Bromide Process.

Any powder colour may be used (writes Mr. T. H. Greenall, in "The Amateur Photographer"), but it must be fine. Paint-shop colours are too gritty, except for large work. The smoke from a small lamp burning turpentine, if caught on the palette, or, better, on a 12 by 10 enamelled iron developing tray, will give a very pleasing black. The powder is made into a stiff paste, with the least possible quantity of Japan gold size, and is then placed in a small covered tin. For use a little about half the size of a pea (for a 10 by 8 print) is spread out on the palette, with one drop of a mixture of one part raw linseed oil and two parts common benzoline. The benzoline quickly evaporates when the paste is spread out, and is only used to dilute the oil. If the paste was originally stiff it may mean another drop of the medium before it will touch even the shadows, but it is best to keep on the hard side and soften very cautiously. At a given moment you will get a pigment which will give all the tones and leave the whites clear, which is what you require. Should extra brilliancy or more vigour be necessary, add one drop of the gold size and less of the oil, but the brush should remain clean, and if you make a mistake, simply wipe off the picture with a rag moistened with benzoline, wash the print with soap and water, and start afresh. This may be done even after the print is dry. A little time and practice is required in order to acquire the "touch" in pigmenting, but as one bromide will serve as long as the paper will hold together, the expense of waste material is negligible.

### Red Tones on Sulphide-Toned Bromides.

The thiocarbamide bath (says Mr. R. E. Blake-Smith, in writing in "Photography," on the method of further toning a sulphide-toned print with gold) is the bath I myself consider to be the best for complete toning, for the brightest red can be obtained by its use. It is best to have three stock solutions:—

1. Gold chloride .....	15 grs.
Water .....	7½ ozs.
2. Thiocarbamide .....	50 grs.
Water .....	7½ ozs.
3. Sulphuric acid (conc.) .....	½ oz.
Water, to .....	20 ozs.

In making up the last solution, the sulphuric acid should be added to about 15 ozs. of water, and then be made up to 20 ozs. with more water. Practically any acid can be used, but sulphuric acid will, I think, be found the most convenient. Solutions of citric acid do not keep well, as a mould grows therein very readily.

To make up the toning bath we take:

No. 1 .....	½ oz.
No. 2 .....	½ oz.
No. 3 .....	½ oz.
Water, to .....	5 ozs.

I think the above is about the best concentration, but No. 1 and No. 2 can be reduced to ¼ oz. each. No. 1 should never exceed No. 2 in amount. As in the case of the sulphocyanide bath, the light parts

are, as a rule, toned to their final colour rather before the darker ones, and so I do not advise this bath for partial toning. A solution of a soluble sulphide seems to have no effect on a print toned with this thiocarbamide solution. This means that all the replaced silver is dissolved away. There will come a time when the thiocarbamide solution will have taken up as much silver as it can hold, if a sufficient number of prints are treated with the same bath. In actual practice the bath should always be thrown away considerably before this point is reached, and a fresh one made up. I have not accurately determined how great a surface of paper it is safe to tone with a given quantity of the solution. For the present I would advise that at least an ounce be allowed for every quarter-plate print. This would make the cost of toning a 12 x 10 print in this manner work out at about 3d.

## New Books.

"Die Binokularen Instrumente." (Binocular Instruments.) By Dr. Moritz von Rohr. Berlin: Julius Springer. 6s.

This monograph on the theory and history of binocular instruments is another of Dr. von Rohr's welcome and characteristic contributions to the literature of optics. Consisting of some two hundred and twenty pages, it bears convincing evidence of the most thorough and painstaking research in English, French, and German literature, the results of which are presented to the reader in a most clear and striking manner. It is, in fact, a model of what such a contribution should be. Dr. von Rohr treats his subject under three heads—*theoretical, historical, and systematic*—the latter consisting of a classification on original lines of the various forms of apparatus dealt with in the historical part. The whole concludes with a very copious and invaluable bibliography of the subject of some twenty pages in length, arranged according to authors. The first part of the book, dealing with the theory of binocular instruments, commences with a setting-out of the conditions which must be satisfied for the true pictorial reproduction of perspective in monocular vision. Passing on to the consideration of binocular vision, the author gives us a strikingly novel and abstract analysis of the varieties of vision obtained by the use of optical instruments. This classification is effected in a simple way by considering how the eyes of an observer are projected into the object-space by optical systems. To take a concrete case, a photographic lens can be made to project a real image of a landscape, which may be viewed binocularly by an observer placed at the necessary distance behind it. Now what Dr. von Rohr does is to imagine the eyes of the observer to be projected by the lens into the space between the lens and the landscape—the object-space—and then consider the disposition of the eye-images thus obtained with respect to the landscape. Obviously in this simple case the eyes of the observer arranged thus  would project thus  with a mirror reversal. In the case of any optical system thus operative for both eyes it is clear that the latter must be projected coherently—i.e., as a whole—a disposition termed "orthoptic" by the author.

When, however, each eye is fitted with a separate instrument, and "if, as before, one now projects the organ of vision  into the object-space, there is no longer any necessity that it shall be projected as a coherent whole, in which the object-eyes of themselves obtain their natural orthoptic setting. If one supposes that the eyes of the observer are inverted by each of the two instruments, then both the natural arrangement  and the crossed arrangement  can occur. The first possibility is realised in the double telescope and the binocular microscope. The second possibility points to a depth arrangement, which, with a simple system inverting the visual apparatus as a whole, is unthinkable, since such apparatus is not forthcoming in nature. Following the analogy of the consequences of the *orthoptic* disposition of the eyes, with this new *chiasmodic* disposition one will expect an unusual depth arrangement, and one is not deceived in this anticipation." In these words is the consideration *inter alia* of pseudoscopic vision introduced. A simple example of what is thus contemplated by the author is the one in which each eye is fitted with a simple reflecting reversing prism, when, as is well known, rays from near points enter the eyes with less

divergence than those from more distant points, with the result that the depth order is reversed and pseudoscopic vision is obtained.

An inquiry as to the possibilities of stereoscopic vision with ordinary stereograms leads to the conclusion that "to the observer looking with like directed eye-axes, orthocentrically arranged, half-pictures offer an orthomorphic picture-space, and chiasmocentrically arranged half-pictures offer a pseudomorphic picture-space, quite independently of how the stereogram is held, since it depends, not upon right or left, but upon whether the necessarily orthopic eye-setting of the observer is presented to an orthocentrically arranged, or a chiasmocentrically arranged stereogram."

We have said sufficient, we take it, to indicate the author's method of treatment, and the remarkable generalisations in which it results.

The historical section of the book, which will probably most commend itself to the majority of its readers, is illustrated with over eighty figures. It commences with a description of the Galilean binocular of Cherubin d'Orleans, with an interocular adjustment, and that remarkable anticipation of the modern stereoscopic range-finder described in Smith's "Compléat System of Opticks" (1738)—a pair of ordinary drawing compasses used to give a stereoscopic pointer of any required length to reach out to an object at a distance; and finishes with an account of Groussilier's range-finder, which the firm of Zeiss has done so much to develop.

Dr. von Rohr's book must, in our humble opinion—such is the completeness and thoroughness of the treatment—establish itself as a classical contribution, which no one in the future, interested in the subject dealt with, will be able to dispense with. Indeed, so well has the author reaped that we shall have nothing but pity for the gleaner, who in the future essays to follow him in the hope of picking up any considerable number of ears of corn left by the way.

F. J. C.

"Camera Work." No. XXI. New York: Alfred Stieglitz.

The last number of "Camera Work" is confined to the pictures of A. L. Coburn, most, if not all, of which are known to our readers who have visited the London exhibitions. An appreciation which accompanies them informs us that black and white has lost all charm for Mr. Coburn, who is now exposing colour-plates upon actresses in gorgeous costumes and jewels, and upon Mr. Shaw (!). The article adds: "He informs us that many of the pictures he has obtained are great." Another article, unsigned, deals with the question, "Is Photography a New Art?" It has cunningly devised premises to its arguments, one being the admittance of dancing as a fine art. Of course, this leaves the door quite sufficiently wide open to let photography creep in behind. The article does not carry conviction, and a painter would find his own art entirely misrepresented. Mr. J. T. Keiley contributes a "Dream of Beauty," commencing with the word "and." The best reading is an excellent article on Donoghue the sculptor, by "S. H." But what it does in "Camera Work" is a mystery.

## New Apparatus, &c.

Imperial Triple-extension Camera (1908 model). Made by the Thornton-Pickard Manufacturing Company, Limited, Altrincham, Cheshire.

The Thornton-Pickard Company, who can fairly claim to have been the pioneers in the manufacture of tourist cameras of the modern type, are to be congratulated on the new model of the instrument which they call the "Imperial Triple-extension," and issue at the popular price of 70s. in the half-plate size, complete with lens, shutter, tripod, and one dark slide. Those whose recollection goes back to fifteen or more years ago will remember the kind of apparatus which a sum even twice this amount would purchase. Such movements, which are now obtainable on the camera before us, could not then be had, even on the most expensive types of apparatus. Modern machinery and a large production have, however, so altered the manufacturers' conditions that a camera produced at a low retail price compares most favourably with the instruments of the higher order, and in this respect, too, the Thornton-Pickard Company have been quick in keeping abreast of the tendency of the trade towards a cheaper class of apparatus, while, on the other

hand, they have placed all their resources in high-class camera building at the disposal of those whose purses are not equal to the demands of the more highly-finished pieces of apparatus. We have reviewed most of the Thornton-Pickard introductions as they have come upon the market, and therefore we can appreciate as well as anyone the points in which the firm has advanced its manufactures from year to year. In the present instance the new model has all the movements which are expected in a camera of the triple-extension type, and, indeed, several which are rarely obtainable even in an instrument costing double the price. As now made, the camera is provided with a rack additional to the two on last year's model,

so that the user starting from the position at which the camera is opened can rack the front forward in the ordinary way to the extent of about 16in.; he can then bring into action a second rack, moving the back to the rear, and obtain the double-extension of the instrument to no less than 22in. Finally, for use with wide-angle lenses, a further rack is provided by which the back of the camera is brought forward so that the distance from the lens flange to the plate is just under 5in. Throughout these movements the user is not left to his own judgment as to whether the plate is square with the camera front. That is settled for him by the manufacturer, and thus provides for the greatest advantage being taken of the modern flat-field lens. It should be mentioned, too, that so well is the camera contrived that even at the short focus great rise of front

can be obtained, and this without any cut-off from the bellows. The point is of importance, because it may easily happen in a less perfectly constructed camera that, while ample rise is provided, it is rendered useless by the internal projection of the bellows' folds. In other respects the fitting of the camera calls for the same commendation which we have been able to extend to it on previous occasions. The nicety with which the brass fittings are rounded instead of being left with sharp corners is a minor point, but, nevertheless, one which makes for comfortable working, and we can honestly describe the instrument as one which is easy of use, for the amateur as well as the professional for that matter, and certainly easy for the dealer to sell. The price of 70s. includes the Thornton-Pickard "Rectoplanat" lens, whilst again at 75s. is fitted with a Beck symmetrical, whilst again at 80s. a Thornton-Pickard "Pantoplanat" is fitted. In each case the outfit consists of a triple-extension camera with turntable top, time and instantaneous shutter, threefold stand, and one dark slide.

Marion's Hot Roller-Squeegee for Dry-Mounting. Sold by Marion and Co., Ltd., Soho Square, London, W.

In this apparatus Messrs. Marion have provided an alternative to the machine press for the now widely adopted dry-mounting pro-

cess. The "squeegee" consists of a heavy metal roller, with polished nickel surface and gas-heated from the inside. The roller is guided over the print by the pair of thick wooden handles, and when not in use is kept on the stand provided with the apparatus. The gas supply is adjustable to give a constant heat, and so long as the roller is kept going pretty well all the time its action is quite even. The

apparatus is certainly a convenient means of carrying out the dry-mounting method, and it may equally be used for cementing celluloid facings to prints, etc., by the hot-rolling method already in vogue. The three sizes of roller (5in., 7in., and 10in. in width) cost 27s. 6d., 35s., and 47s. 6d. respectively, which prices include the stand and two zinc plates of appropriate size.

The "Blackall" Developing Dish. Made by Marion and Co., Ltd., Soho Square, London, W.

This dish is made with the special object of facilitating the handling of large plates, an end which it achieves in two ways. It is made with a well and glass bottom, so that the negative can be examined without having to remove it from the dish; and secondly, there is provided a plate-lifter by which, on the conclusion of development, the plate is raised from the dish and readily removed. The plate-lifter has two practical features about it which call for com-

mendation. It runs the length of the plate, exerting an equal thrust on the whole plate, and thus obviating the fracture which can easily be caused by suddenly raising a large plate from one point. In addition to this, the bearings in which the lifter moves are disposed on the outside of the dish away from contact with the developing solution. The dish is strongly made in wood, the joints and body are cemented water-tight, and altogether it is an article eminently fitted for regular practical use, the sort of appliance, in short, which one usually has to get made oneself, because there is nothing on the market like it. The three sizes in which the dish is made are named Nos. 1, 2, and 3. No. 1 (5s. 6d.) takes three half-plates; No. 2 (7s. 6d.) holds one 12 x 10 or two whole-plates, and No. 3 (10s.), takes a 13 x 12 or 12 x 10.

THE A. E. G. PROJECTOR NERNST LAMP.—Since reviewing the lamp some weeks ago, when we were able to speak favourably of it, we have had sent to us an illustration of the lamp, which may appropriately supplement the previous reference, inasmuch as it is almost exactly one-half the actual size of the lamp. The latter

measures over all 8in. by 4½in. by 6½in. The A. E. G. English Manufacturing Company, Limited, 4 and 5, New Compton Street, Charing Cross Road, London, W.C., will send full particulars of

the lamp on application. The new introduction certainly offers the advantage, for printing and enlarging purposes, of great power and steadiness.

ART MOUNTS.—A series of art-mounting papers in a variety of surfaces and substances are supplied by Messrs. F. E. Jones and Co., 22, Gray's Inn Road, London, W.C., to the number of about a score. The book of numbered specimen sheets should be applied for and preserved at hand for reference, since it shows at a glance the selection of textures and colours available. The mounts are supplied in thick and thin substances on sheets 25 by 20½, at 8s. and 4s. per quire respectively.

#### CATALOGUES AND TRADE NOTICES.

A NEW MODEL of projection lantern has been brought out by Messrs. Bausch and Lomb, and is described in a circular just issued by Messrs. A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, London, E.C. The lantern is of a very solid lathe-bed construction, yet is lighter and lower in price than the firm's previous lanterns. It is adaptable to microscopic projection.

MESSRS. WILFRED EMERY, LTD., of 89, Cricklewood Broadway, London, N.W., send us their latest price list for printing, developing, toning, enlarging, etc., for both amateurs and the trade. The prices are moderate, and the quality of the work eminently satisfactory. The firm also undertake the repair and exchange of cameras, and also supply second-hand cameras at low prices.

WHAT TO WEAR TO THE STUDIO.—"There is a tremendous amount of ignorance on the subject of colours. Very frequently a woman wears a gown of a certain colour, yellow, for instance, expecting it to take light, when it takes dark, and is, consequently, disappointed in the result," says a photographer in the "New York Sun." "White is always effective, and takes beautifully, especially for dark background effects. But light blue, pink, or cream are preferable even to white, for the reason that while they take light there is more detail and more character in the picture."

"If possible, soft, clinging effects are to be preferred to any material that presents a stiff appearance, and starchy effects should be tabooed entirely."

"Nowadays nearly every photographer has on hand lengths of soft, clinging material for drapery purposes when his subjects present themselves with some absolutely impossible frocks and when he can effect the substitution without hurting their feelings."

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### FRIDAY, JANUARY 31.

Cardiff Photographic Society. "A Collection of Slides." S. C. Fox.  
 Dunbridge Wells Amateur Photographic Association. Annual Meeting.  
 Paisley Photographic Society. Rotary Carbohydrate Paper.  
 Monday, February 3.  
 Bedford and Forest Hill Photographic Society. "Carbon." The Autotype Company.  
 Southampton Camera Club. Lecture Competition.  
 Bradford Photographic Society. "Yorkshire—Historic and Picturesque." George Hepworth.  
 Scarborough and District Photographic Society. Y.P.U. Lantern Slides.  
 Harrow District Photographic and Scientific Society. "Sewage and Sewage Disposal." C. Sordes Ellis, F.I.C., F.C.S.  
 Kidderminster and District Photographic Society. "Wild Life." C. A. Allen.  
 Lancaster Photographic Society. "Time Development."  
 South London Photographic Society. Rotary Carbohydrate Paper.

#### TUESDAY, FEBRUARY 4.

Royal Photographic Society. "The Oil-printing Process." John H. Gear, F.R.P.S.  
 Hanley Photographic Society. "Platinotype." Rev. C. F. L. Barnwell.  
 Keighley and District Photographic Association. Y.P.U. Lantern Slides.  
 Rotherham Photographic Society. "A New Carbon Paper." W. D. Welford, F.R.P.S.  
 Stafford Photographic Society. "Flashlight Photography." S. T. Davies.  
 Hackney Photographic Society. Annual Concert.  
 Sheffield Photographic Society. "The Dales and Coast of Yorkshire." Godfrey Bingley.  
 Manchester Amateur Photographic Society. "Tank Development." R. O. Gilmore.  
 Staines and District Photographic Society. "Enlarging on Various Grades of 'Rotograph' Bromide Paper."  
 Sutton Photographic Club. "Rambles with the Camera."

#### WEDNESDAY, FEBRUARY 5.

Coventry Photographic Club. Judging No. 1 Winter Competition.  
 Leeds Camera Club. "Genre and Figure Studies." T. Lee Symms, F.R.P.S.  
 Woodford Photographic Society. "The Romance of Insect Life." F. Martin Duncan.  
 South Suburban Photographic Society. "Afar in the Fatherland." W. L. F. Wastell.  
 Borough Polytechnic Photographic Society. "The Lumière Autochrome Plate." W. Page.  
 Bristol Photographic Club. "Marine Photography." F. J. Mortimer, F.R.P.S.  
 Central Technical College Photographic Society. "Gum-Bichromate." D. R. Pincock.  
 Mill Camera Club. "Prize Slides." "District Times."  
 North Middlesex Photographic Society. Lantern Slide Competition.

#### THURSDAY, FEBRUARY 6.

Blenheim Club. "Memories of a Marshland Minister." (Ely Cathedral).  
 Bath Photographic Society. "Pictorial Photography." W. Rossiter.  
 Liverpool Amateur Photographic Association. "Oil Printing." Chas. F. Stuart.  
 L.C.C. School of Photo-Engraving and Lithography. "Electric Light and Motors as used by Photo-Engravers and Printers." A. C. Jolley.  
 Worthing Camera Club. Rotary Carbohydrate Paper.  
 Nottingham Camera Club. "Autochrome Plates." R. Child Bayley.  
 Handsworth Photographic Society. "Landscape Enlarging with the Introduction of Clouds." E. G. Collins.  
 Hull Photographic Society. "Platinotype." Demonstrated. Rev. Joseph Bealand.  
 Chelsea and District Photographic Society. "Figure Study." E. T. Holding.  
 Rugby Photographic Society. Royal Photographic Society's Affiliation 1907 Prize Slides.  
 Queen's Park Amateur Photographic Association. "City and Night Photography." Robert Gracie.  
 Midlothian Photographic Association. "Printing in Gaslight Papers." J. B. Johnston.  
 Wimbledon and District Camera Club. "Colour Photography by the Pinatype and Autochrome Processes." W. H. McMillan and Dr. J. H. Wilson.  
 Tunbridge Wells Amateur Photographic Association. "A Chat on Impressionism."  
 Richmond Camera Club. "A Visit to Holland." E. Fincham.

### ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, January 28, the president (Mr. J. C. S. Mummery) in the chair.

Mr. Frederick H. Evans delivered a lecture in reference to the opening of an exhibition at the rooms of the society of examples by himself of the multiple mounting of photographs. A review of the exhibition itself appears on another page. Mr. Evans dealt first with the correct placing of a print on the mount irrespective of the use of several mounting papers. The position in which the print was placed by professional mounters was, he pointed out, the centre of the mount, but it was a bad position, because it made the print appear as though actually dropped below the centre. There was a correct position for it, which varied with the shape of the mount and the particular effect which it might be desired to emphasise, but a good rule was to leave more space below the print than above it, and about the same space on each side as that above the print.

The lecturer handed round examples, which clearly demonstrated these points. In a brief reference to the frame, Mr. Evans said that choice should be made as to whether frame or mount was to be responsible for the decorative presentment of the print. If mounting was to do it then the frame should be simple, and, similarly, if elaborate framing was adopted then the mount should be of the simplest description. Speaking of the tone of mounts, whether light or dark, the lecturer showed examples of the way in which a light mount enhanced the dark tones of a print, and showed comparative examples, proving the greatly dissimilar effects obtained with identical prints from the suitable choice of the mounting papers. He also exhibited prints differing in contrast, which had been equalised by the selection of different mounting schemes. A full and useful description of his methods would require the study at the same time of the sixty examples shown at Russell Square, and those who are interested in the matter should obtain the full text of the paper when it is reprinted in the society's journal of February 16, and study the exhibition in conjunction with it.

Turning to practical methods, Mr. Evans said his own plan was to cut up a goodly quantity of the mounting papers into pieces of convenient size and keep them sorted out into the various tones and colours, such as grays, light greens, dark greens, and so on. When selecting mounting papers for a print the latter was held in the hand and a mounting paper placed behind it, roughly registering one upper corner of the print with that of the mount so as to produce a narrow border of mounting paper. In the same way a further mounting paper was placed behind the first, and in this way—holding the mounts in the hand, a pretty good idea could be obtained of the various effects. When it came to actually making the mount, Mr. Evans attached the mount by the two top corners to the first mounting paper with a good mountant of the dextrine class. The mounting paper was then trimmed down equally all round with a guillotine, taking special precautions to preserve absolute straightness of trimming. The print itself also should be trimmed exactly square to start with. In this way the mount was built up behind the print. As regards the selection of the papers, nothing but the worker's own practice and taste would tell him what to do, but one obvious rule derivable from Mr. Evans's examples was to avoid repeating borders of equal width round the print. The width of these latter should be contrasted and adjusted to emphasise or to diminish certain effects in the print. The stronger colours should only be used in very narrow bands in the mounting scheme, and the most useful series of mounts were those which contained a variety of low tones, such as grays, dark and light browns, greens, and blues. An important matter in making use of the mounts was the alteration in tone which was produced by placing, say, a light band between two dark ones; the effect was different from that obtained when not thus bordered.

Mr. Evans's lecture amounted to a direct demonstration of his methods, and an interesting discussion followed, in which a number of speakers brought up one or two various points, among which was the fact that all Mr. Evans's prints were on platinotype paper, and that, therefore, he had not found it necessary to use a dry mounting method. In the case of carbon or bromide prints, he considered that dry mounting would be necessary. Most of his own mounting papers were those imported by Lindenmeyer, but other speakers spoke in favour of the art-mounting papers obtainable from Barton's, of Birmingham, and from Houghtons Limited. Another speaker mentioned the automatic Merritt trimmer as excellent for multiple-mounting work. A point raised by another speaker was the inconvenience occasioned by the impossibility of studying the pictures in conjunction with the text of Mr. Evans's paper. Mr. C. P. Butler suggested that the proof of Mr. Evans's article should be available in the exhibition-room during the time the pictures were on view, but it was stated from the chair that the text of the paper would not be so available until its appearance in the "Photographic Journal" for February 16.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

Ordinary meeting January 23, 1908. Mr. E. T. Wright in the chair. Mr. A. R. Smith passed round a film negative made through a half-tone screen of about 130 lines to the inch, which, when held to the light showed chromatic effect, in some positions almost giving a small spectrum.

Mr. H. C. Rapson, said that when copying pictures with a white border one almost invariably got this effect.

Mr. Teape produced two bottles of pyro developer that were unearthed from the library cupboard on the 16th, and which he had taken away on that date to try. The bottles were only part full, and had had no care whatever bestowed upon them beyond the glass stoppers. The labels showed that they were made on January 15, 1891, and they had been since that date at the meeting room. He had used these upon a number of plates. On bottle No. 1 the formula was:—

Pyro .....	1 oz.
Acid sulphurous .....	1 oz.
Water .....	9 oz. 1 dram.

For his first test he took of the above solution 15 minims, soda sulphite 10 grains, soda carbonate 8 grains, potass. bromide 3-10 grain, water 1 oz. The plate developed in  $1\frac{1}{2}$  minutes to a fine black tone.

Second test:—10 minims of above solution, soda sulphite 8 grains, soda carbonate 6 grains, potass. bromide 3-10 grain, water 1 oz. In this he developed three plates, all of which were a good black.

Yet again he took 10 minims of the old solution, soda carbonate 6 grains, potass. bromide 3-10 grain, water 1 oz. The plate developed in this in just under four minutes and showed a slightly yellow tinge. At the same time it must be carefully noted that here no soda sulphite was used, thus proving at once that this salt has an effect upon the result; both as to time of development and colour of result.

Bottle No. 2 had a solution of

Pyro .....	1 oz.
Soda sulphite .....	4 oz.
Water .....	30 oz.

Of this he took 33 minims, soda sulphite 8 grains, soda carbonate 6 grains, and water to 1 oz., potass. bromide 3-10 grain, and developed two plates. The development was rather slow, being in the first case five minutes, and in the second ten minutes, but the image was of a fine black tone without any tinge of colour, and as a check upon his work he used another plate with freshly mixed developer as follows:—Soda sulphite 8 grains, soda carbonate 6 grains, potass. bromide 3-10 grain, water 1 oz., adding immediately before development of dry pyro 1 grain. Time of development,  $2\frac{1}{2}$  minutes. This plate, though of a good black colour, did not yield so fine an image as did the old solutions.

The results, he thought, were valuable, as they proved that pyro solutions could be kept almost any length of time and still do the work. It should be noted that the bottles were only part full, and not filled to the stopper, as is advised when making solutions with an idea of long keeping.

Mr. Stretton pointed out that the results rather upset the ideas set forth in Messrs. Mees and Shephard's paper as to soda sulphite not having any action upon the developer.

Mr. Teape said it had a very great action.

Mr. Stretton was using pyro developer nearly a year and nine months ago with potass. metabisulphite and got no stain.

Mr. Finlay asked if the bottles had been opened say, once a week, would it not have made a difference? As the opening would have admitted more oxygen, whereas only a certain amount had been corked up, so to speak.

Mr. Human said that when using ortol the addition of soda sulphite had, he found, a very marked effect, slowing down the time of development to as much as ten times, according to the amount of sulphite added.

Anyone interested may see the bottles of developer and examine the results at the New Rooms, Ye Olde Napier Tavern, 25, High Holborn, W.C., at any meeting after February 6, 1908.

**STAINES AND DISTRICT PHOTOGRAPHIC SOCIETY.**—At the annual general meeting, held on January 22, the reports presented by the energetic secretary, Mr. C. J. Fox, and the treasurer on the completion of the society's first year, were highly satisfactory. After the election of officers an exhibition and competitions for members were held, resulting as follows:—Class A.—Contact Prints: 1, Mr. Hoare;

2, Mr. Rule; 3, Mr. Leake. Class B.—Enlargements: 1, Mr. Fox certificate, Dr. Thompson. Class C.—Lantern Slides: 1, Mr. Neaves; 2, Mr. Rule; 3, Dr. Thompson. Both competitions and exhibition produced some excellent pictorial work from the members, prominent among which was work of particular merit from Mr. Rule, Mr. Fox, and Dr. Thompson, the last-named of whom sent in a fine exhibit of telephoto work with the Adon lens.

**WOOLWICH PHOTOGRAPHIC SOCIETY.**—At the meeting, held January 23, a paper was read by Mr. G. T. Gale on "Jenolan Caves of Sydney, N.S.W."

**CENTRAL TECHNICAL COLLEGE PHOTOGRAPHIC SOCIETY.**—On Wednesday, January 22, Mr. Jackson, of the Rotary Photographic Company Ltd., gave a very able and interesting demonstration of "Carbograph," the new enlarging carbon tissue, which was greatly appreciated by those present.

**CROYDON CAMERA CLUB.**—Annual meeting. The report shows a very satisfactory state of things. Since the club's removal to more commodious and more expensive premises, it has required not a little skill and contriving to make both ends meet. Not only has the hon. sec., Mr. H. M. Bennett, succeeded in doing this but he was able to announce a record cash balance in hand of nearly £40. Thanks largely to the untiring energy of a small band of workers, the recent exhibition shows a profit of about £15. Mr. A. E. Isaac, the popular president for the year, retires, his place being taken by Mr. J. M. Sellors, unanimously elected. Owing to pressure of business Mr. F. W. Hicks relinquishes his post of treasurer, an office he has filled remarkably well. Mr. Alexander succeeds him, and Mr. Bawcomb becomes assistant honorary secretary.

**SOUTHAMPTON CAMERA CLUB.**—Mr. Arthur Marshall gave his lecture, entitled "Some Spanish Scenes and People, and a Bull Fight," on Monday evening last, before a crowded audience.

The lecturer at the outset described some interesting features to be seen at Biarritz, and gave his experiences of the railway journey over the Pyrenees. He referred to the somewhat tedious railway travelling, which, however, enabled him to secure some excellent photographic panorama views of the country scenery from the carriage window. Mr. Marshall then gave particulars of his impressions at San Sebastian, and, with some excellent slides, he pointed out many of the architectural features, including the palatial marble buildings which are so noteworthy. Burgos was also referred to, and the picturesque slides of the market scenes and the Old Gateway were lucidly described.

Madrid proved rather disappointing to the lecturer from a picturesque standpoint, and the general impression conveyed was uninteresting. Some interesting types of people seen in the capital were illustrated, and the allusions to the difficulties encountered in securing these photographs were extremely amusing. Mr. Marshall, in conclusion, gave a vivid account of a bull-fight he witnessed, and the slides illustrating this form of Spanish entertainment proved convincing proof of the brutality which was correctly termed "a real tragedy in three acts." A hearty vote of thanks, proposed by Mr. A. E. Henley and seconded by Mr. S. G. Kimber, was carried with acclamation.

**A LIMERICK PRIZE-WINNER.**—Mr. Arthur Squibbs, photographer, Napleton House, Warren Street, Tenby, who three weeks ago was awarded a first prize of £57 18s. in the "News of the World" Limerick Competition, last week won a second consolation in the same paper.

**THE DRESDEN INTERNATIONAL EXHIBITION.**—The following gentlemen have consented to serve on the English Committee of the above exhibition:—A. H. Blake, Arthur C. Brookes, Geo. E. Brown, C. P. Butler, F. Martin Duncan, A. Horsley Hinton, F. J. Hollyer, F. J. Mortimer, Rev. F. C. Lambert, J. C. S. Mummery, Furley Lewes, H. Snowdon Ward. The Honorary Secretary is Mr. E. O. Hoppe, 10, Margravine Gardens, Baron's Court, London, W.

"A SCAMPER THROUGH HOLLAND" is the title of a lecture by Mr. W. F. Slater, which, accompanied by 152 lantern slides, the Zealand Steamship Company, of Electra House, Finsbury Pavement, London, E.C., will be pleased to lend to photographic societies and others free of charge.

## Commercial & Legal Intelligence.

**EASTMAN KODAK COMPANY OF NEW JERSEY.**—The usual quarterly dividend of  $1\frac{1}{2}$  per cent. (being at the rate of 6 per cent. per annum) on the outstanding preferred stock, and of  $2\frac{1}{2}$  per cent. (being at the rate of 10 per cent. per annum) upon the outstanding common stock of the Eastman Kodak Company of New Jersey, will be paid April 1 to stockholders of record on February 29, 1908.

**PHOTOGRAPHERS FINED.**—David Selman and Emanuel Harris, engaged by a "free portrait" canvassing firm, were summoned at the Bristol Police-court last week, the former for travelling without having paid his fare, but with a season ticket made out in the name of Harris, who was known to have used the same ticket the evening before, and the latter for aiding and abetting him in so doing. They were fined forty shillings and costs each, a guinea solicitor's fee being allowed the defendant Harris.

**THE AFFAIRS OF A DERBY PHOTOGRAPHER.**—On Saturday a meeting of the creditors of Frederick Vogel, photographer, residing at 16, Portland Road, Nottingham, and lately carrying on business at Jackson's Chambers, St. Peter's Street, Derby, was held at the office of the Official Receiver in Bankruptcy at Derby. The gross liabilities amount to £268 16s. 9d., of which £250 14s. 9d. is expected to rank for dividend. The assets are estimated to produce £91 18s., the deficiency being £158 16s. 9d. The bankrupt, who was formerly a canvasser for a New York firm, principally attributes his loss to a stock of enlarged photographs not being taken up by customers which, including cost of soliciting orders, came to £250. No resolutions were passed, and the estate remains in the hands of the Official Receiver, Mr. F. Stone, Full Street, Derby.

**SATINO, LTD.**—The affairs of Satino, Ltd., were inquired into by the Official Receiver at the Offices of the Board of Trade, in Carey Street, on January 22. Mr. Nunn, a director of the Company, and Mr. Pepper, a former director, were present.

The Official Receiver asked Mr. Nunn to explain why no statement of affairs had been filed. It was a very serious default, and would be reported to the Registrar.

Mr. Nunn: I have done my best.

The Official Receiver: It is through you that the creditors are wanting their debts paid and you should make an effort when you have brought things to such a grievous condition.

Mr. Nunn: I have made every effort.

The Official Receiver: I don't think you have. It is two months since the order was made, and the responsibility for the condition of the books must largely rest with you.

In relating the history of the Company, the Official Receiver said it was floated in February, 1907, with a capital of £500 in £1 shares. The object was to take over the photographic department of a business with which Mr. Nunn was connected. Mr. Nunn was appointed experimental photographer and drew £2 a week. The goodwill purchased by Satino, Ltd., consisted of an agency for the sale of certain German photographic paper in this country. Previous to the flotation of Satino, Ltd., the Nunn Company issued some debentures covering the whole of the stock purchased by the new Company. The debentures were now held by Farrow's Bank, who had appointed a Receiver. The realisation was not likely to produce sufficient to pay off the debentures. The total unsecured liabilities were £1,000.

Mr. Nunn, in explaining the position of affairs to the creditors, said if it had not been for the bad season of 1907 the Company would have done good business. They were using a sun-ray medium for the photographic work, and the dull summer rendered it useless. If the business could be tidied over to next year he believed it would do well. Mr. Nunn suggested the formation of a new concern, in which the creditor of Satino, Ltd., would be allotted shares, and in which it might be arranged that the debenture holders in Satino should hold ordinary shares instead of debentures.

The representative of Messrs. Johnson and Son, manufacturing chemists, remarked that this proposal seemed to be the creditors' only hope.

No resolution as to the appointment of a liquidator was passed, and it was left to Mr. Nunn to develop his proposal.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

### USEFUL AWARDS AT THE LONGTON EXHIBITION.

To the Editors.

Gentlemen,—It may interest your readers to know that one of the features of the above exhibition will be another departure from the conventional plaque and medal as awards.

The judge is to have placed at his disposal twenty-four awards which will take the form of ornamental vases or other artistic and useful local pottery productions in china or earthenware, for which this district is noted.

This course has been adopted in deference to suggestions from lecturers at the society's meetings, who, having in their possession a superfluity of medals obtained at various exhibitions, expressed a wish that something more useful might be awarded as prizes.

The committee hope that the change will meet with the approval of exhibitors generally, and that it will add to the success of our show.—I am, yours faithfully,

E. CARRATT.

(Member of Exhibition Committee.)

### THE KALLITYPE PROCESS.

To the Editors.

Gentlemen,—An article by me published in the October, 1906, issue of the "Photo Era," the title "The Kallitype Process," you were good enough to reprint in a later issue of your journal. In the article as originally published was a regrettable error, which, of course, was carried along to your reprint. The fact that my process has still further exploitation in the latest "B.J." Almanac prompts me to thus communicate with you in the effort to correct the mistake. The original typographical error I sought to correct in a later number of the "Photo Era," but in making the correction still another blunder was made, therefore I thought it about time to give it up.

The mistake occurs in prescribing a *drachm* of oxalic acid in the diluted developer where a *grain* is what should have been. The corrected formula for developer stock solution should read as follows:—

Distilled water .....	1 oz.
Silver nitrate .....	40 gr.
Citric acid .....	10 gr.
Oxalic acid .....	8 gr.
Phosphate of soda .....	$1\frac{1}{2}$ gr.

When thoroughly dissolved, decant, or filter through a piece of fine linen.

To develop, take one (1) drachm of stock solution to every seven (7) drachms of water.

Worked as it should be, this process gives beautiful platinum-like prints, but the error in formula would result in absolute failure—flat, faded pictures, fit only for the waste basket.—Very truly yours,

129, Bird Street, Dorchester, Mass., U.S.A.

January 15, 1908.

JAMES THOMSON.

### PRINTING VIGNETTES BY ELECTRIC LIGHT.

To the Editors.

Gentlemen,—I have tried several ways of printing vignettes by this method, but only find three satisfactory, which I have much pleasure in explaining for the benefit of my fellow-readers of the "B.J." To print vignettes quickly, and at a distance of about 10 in. or more from the electric-arc lamp, I found the best method was to make several good vignettes on P.O.P. by exposing same to daylight in the printing frame behind a piece of clear glass with ordinary vignetter fixed in front. I then toned these to a good

colour and fixed them. When dry I copied them in the camera to the size required, making as good a negative as possible, with full density and clear vignette in centre, then placed vignette negative in printing frame, film side in, and next adjusted the negative and paper to be printed from and exposed. I recommend this method as the ordinary celluloid vignettes sold on the market will not stand the heat, and cockle up in all directions. Glass negatives will stand an enormous amount of heat before cracking. At 10 in. distance from lamp I have not had a single one cracked yet. This method prints in about the usual time. You can also use paper vignettes made the same way, only the grain of the paper takes much longer to print as compared with clear glass.

The next way of printing is by placing the ordinary vignetter in front of the printing frame, containing negative and paper, and fixing a piece or two of tissue paper or thin linen in front of this, supported on two pieces of wood about  $\frac{1}{4}$  in. thick, fixed to vignetter, thus:—

The frame need not be moved round, and it prints in about ten minutes. At 10 in. from the arc lamp you can get a circle of six half-plate frames, and work them three deep, making eighteen frames round the light.

Another method is to place the ordinary vignetter in front of the frame containing the negative and paper, to hold same to lamp, and to turn it continually round. This method prints in about four minutes, and any boy can work it. Any further particulars which any reader would like I shall be most pleased to give.—Yours truly,

THOMAS E. STAGG.

The Imperial Postcard and Printing Co.,  
128, Bromley Road, Catford, London, S.E.

#### STAMPING MOUNTS, ETC.

To the Editors.

Gentlemen,—A correspondent inquires as to the way to use a punch for stamping mounts, etc. The following is the best way:—On a smooth slab of stone or metal lay a thin card, on that the mount, and hit the punch with a wooden mallet instead of a hammer.

Manchester, January 25, 1908.

D. B.

#### THE "B.J." IN ASIA MINOR.

To the Editors.

Gentlemen,—We do not know that it will interest you, but might mention that this morning we had an inquiry in answer to our advertisement in the "B.J." from Turkey, in Asia. We thought that you might like to mention this in your columns, as we do not suppose that there are many who know that your journal reaches quite so far as this. We, at any rate, did not know it.—We beg to remain, faithfully yours,

A. KING AND SON.

37, High Street, Littlehampton.

January 27, 1908.

#### PHOTOGRAPHERS AS PROFESSIONAL MEN.

To the Editors.

Gentlemen,—Anent your article in last week's "Journal," "Should the Photographer Pose as a Professional Man?" my reply as one is a decided Yes, and I feel assured that the majority of photographers will join with me in this opinion. Something certainly ought to be done to raise the standing of the photographer, who at present is a kind of pariah and outcast, without status; in fact, the word "photographer" carries with it a sort of stigma, and means social ostracism. Not only many of our leading men but also a number of the rank and file are gentlemen by birth and education, who have soul and ideals in their productions, conveying an atmosphere which proclaims the artist and not the mere money-grubber.

In your issue of the 20th ult. I note a very able article by Mr. C. H. Claudy, in the latter part of which, in "Professional Photography de Luxe," I come across the following paragraph: "There is many a tradesman who loses trade, photographer or butcher." But why class them together? The latter is certainly a tradesman and the former a professional man, with just as much right to use a brass plate as Messrs. Quill and Parchment, and also classed as an artist in the Copyright Act of 1862. Is it not possible to have an Incorporated Society of Photographers, similar to accountants, dentists, etc., thereby weeding out the unfit (of whom, alas! there are far too many) and raising the standard of the profession? If this is impossible doubtless some of your readers can suggest a remedy, or yourselves with your all-powerful journal; but do not, gentle Editors, I beseech you, stigmatise us as tradesmen.—I remain, yours faithfully,

STATTS.

[We shall be glad to hear the views of any other readers. We refer to another aspect of the matter this week.—Eds. "B.J."]

#### CARBON PRINTS ON JAPANESE VELLUM PAPER.

To the Editors.

Gentlemen,—In a recent issue you recommended the use of Japanese vellum paper as a final support in carbon printing under certain circumstances. You also gave the name of the importers of this paper, Messrs. Crompton and Co., who have since written to us in connection with the matter. Owing to the article in question, they have received numerous inquiries from photographers and others, but being wholesalers they do not wish to be troubled with small accounts. We have consequently made arrangements to deal with any inquiries they may receive, and we have selected a suitable paper from their stock, which we are coating up, both for single and double transfer final support, and supplying it at 1s. per sheet, size 29in. x 22in.—With compliments, yours truly,

THE AUTOTYPE COMPANY.

C. Sawyer.

74, New Oxford Street, London, W.C.

January 23, 1908.

#### COPYRIGHT IN POSTCARDS.

To the Editors.

Gentlemen,—Your answer to "Bert Hole," in this week's "Journal," is a most interesting one to many photographers, but I cannot help thinking that you are mistaken. Are we to understand that whenever a person who figures in a postcard purchases one of the said cards, he can stop the producer from publishing any more, and actually compel him to call in those already sold? This seems altogether unreasonable, yet it is practically what you infer by your reply.

These people did not engage "Bert Hole" to photograph them or their farm, but were asked to pose in the picture by him. Would the purchase of one postcard give them the right to stop his sale, and if not, how many must they buy to give them this right? If you are correct in your answer I am afraid half the postcards now on sale may be stopped by any cantankerous person who happens to appear on them and buys the card for one or two pence.—Yours faithfully,

St. Mary's, Isles of Scilly.

January 27, 1908.

C. J. KING.

[Our correspondent must allow us to repeat that the case instanced by "Bert Hole" is a "nice point," and, further, that our reply was advice to our querist as what he had best do in the particular circumstances. Our advice amounted to the recommendation to abstain from contesting the matter and to keep the dispute out of the lawyers' hands. We are quite aware of the rights of the photographer in any view which he may take, but it might be argued, in reference to the farmhouse scene, that the permission to photograph the house with a view to sales constituted a "valuable consideration" to the photographer. Our correspondent might refer to the case of *Stackemann v. Paton*, which involved a nice distinction, such as this, and was fully dealt with in the "B.J." for April 20 and May 4, 1906. There is, of course, no doubt at all that the photographer owns the copyright when there is no sort of payment to him for his work. Our correspondent is arguing too quickly from the particular to the general.—Eds. "B.J."]

## Answers to Correspondents.

*All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*

*Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*

*For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

W. Gaskell, 3, Piercy Terrace, Piercy, Waterfoot, near Manchester: Two Photographs of a Motor-Bus.

**PHOTOGRAPHY IN CAIRO.**—(1) Is there any scope for photography there? (2) Should you think there would be any likelihood of getting a situation as assistant, either to a photographer or photographic chemist or dealer? (3) What is the cost of getting there, say from London? (4) What paper would be best for advertisements there?—E. A. WALES.

(1) Undoubtedly a good deal of business to be done in requisites for amateur photography, and, we should say, in professional portraiture. (2) We can only say that it is possible. (3) Apply to Thomas Cook and Son, Ludgate Circus, E.C. (4) The Cairo newspapers are "Le Caire," "Le Journal," and "Les Pyramides," all of which appear daily.

**WASHING PRINTS.**—Will you kindly inform me (1) how long washing by hand albumen prints should have to ensure permanency, (2) If gelatine chloride prints, toned and fixed in the following bath for fifteen minutes, allowing 2 grs. gold per sheet, will be permanent: Hypo, 5 ozs.; lead acetate, 1 dr.; gold, 4 grs.; water, 40 ozs.?—EN AVANT.

(1) If you mean "by hand" that prints receive fresh water round them as often as every five minutes, one hour's wash—i.e., twelve changes—is ample. (2) The bath is rather weak in hypo; at least three ounces per pint should be used. A better composed bath is that on page 866 of the "Almanac."

**C. H. A. D.**—(1) Can only suggest you apply to Mr. Warwick Brooks, 350, Oxford Road, Manchester. (2) An R.R., with aperture f/8, is quite rapid enough, and covers far better. (3) Your query is altogether too large a question. Each light has its good points. See the recent articles and correspondence in our columns.

**BARYTA PAPER.**—Would you be kind enough to give me a formula of some kind for baryta paper coating? I wish to baryta coat some raw paper, and what suitable dye would you recommend to tint it, of course, like the paper at present on the market?—SAM JONES.

As a rule, the baryta is prepared by treating carbonate of barium with sulphuric acid till there is no longer effervescence, then washing and drying. There should be from 8 to 10 parts of hard gelatine to every 100 parts of baryta, and, of course, the necessary quantity of water. For the colours, alizarine lake is used for the red, Prussian blue for blue, and a mixture of the two for mauve. The quantities depend entirely on the depth of tint required.

**A. CLARKE.**—Thanks for cutting. You see, we refer to the subject on another page.

**INSURANCE OF STUDIO.**—Can you quote me the usual rate for insurance of studio, attached by corridor to house in front, studio being built of brick, wood, and glass?—INSURANCE.

We cannot quote the rate, as we know very little of insurance business, so far as the premiums are concerned. If, however, you inquire of any of the agents for the different insurance companies,

of which there are doubtless several in your town, they will give a definite quotation. The Professional Photographers' Association arranges a special rate for its members.

**COATING MACHINE.**—Will the experimental coating machine, given in the "B.J.," April 26, 1907, p. 314, be suitable for coating sheets of celluloid (instead of paper) with a gelatine emulsion? If not, could you tell me what alterations would be necessary to make it suitable? Is the paper used with this machine in a continuous roll? If so, of course, it would be necessary for the celluloid to be similar.—THOS. J. FAIRFIELD.

It would be quite possible to use the machine for coating celluloid; but sheet celluloid, that is, of the usual thickness of the ordinary cut film, cannot be obtained in rolls. It might be feasible, however, to cement the sheets together so as to form a roll, as is sometimes done in the case of paper.

**PYRO-SODA.**—Some months ago you published a formula for pyro-soda developer, under the heading of "A Pyro-Soda Developer that will keep." I have unfortunately lost the formula. Would you kindly repeat?—R. E. WESTON.

A. Soda sulphite .....	2 ozs.
Potass metabisulphite .....	½ oz.
Pyro .....	160 grs.
Water to .....	20 ozs.
B. Soda carbonate .....	4 ozs.
Water to .....	20 ozs.

Use equal parts of each. This formula appeared in our issue for September 28, 1906. You will find some further notes on the subject in the 1908 "Almanac," page 625.

**TONING BROMIDES.**—Will you kindly, in "Answers to Correspondents," say where I can get mercuric bromide, as per formula (sulphide toning bromide prints), in your issue of January 17? I have applied to two chemists, and neither know nor have heard of it.—OBBO.

You can prepare the solution, as advised by our contemporary, "The Amateur Photographer," from which we quoted, by dissolving 120 grains mercuric chloride, and 120 grains potass bromide, in water, 10 ozs. Forty minims of this solution correspond to 1 grain of mercuric bromide.

**PRICES FOR LANTERN SLIDES.**—I should be much obliged if you would answer in your customary column the two following questions:—

(1) What is the average charge made by professionals for producing lantern slides from customers' own negatives? (2) What would be a reasonable charge for producing lantern slides from book plates and manuscripts, or from original scenes? I am, of course, assuming that only one copy is required of each.—MIDLANDER.

A fair charge is a shilling for each slide, and the same for each negative, when working from a print or other original.

**PROCESS WORK.**—Will you kindly inform me (1) if the line block process (not half-tone) can be worked on a small scale, if you want special apparatus for it, and also if there is a book on the process? If so, kindly let me know where to obtain it, with price of same, if possible. (2) Will you please give me the address of Walter Carson and Sons, manufacturers of Vitrolite, for frosting the glass in studios, as mentioned in the "B.J. Almanac" for 1905?—ZOUCH.

(1) No special apparatus is necessary, beyond a whirler, etching troughs, and inking rollers. You had better get "Photo-Mechanical Processes," by W. T. Wilkinson, published by Hampton and Sons, price 4s. (2) Grove Works, Lombard Road, Battersea, London. S.W.

**GLAZING P.O.P.**—I should be glad if you could give me a method of procedure for glazing P.O.P. prints on glass. I have had them stick badly sometimes, and at other times it has been a pleasure to do the glazing. If you can help me in any way I should be glad.—C. W. WARD.

Your trouble has possibly something to do with the weather. As you say nothing of your procedure we can only suggest that you give the prints ten minutes in 5 per cent. alum solution, after washing from hypo, and a further ten minutes' wash after the alum. You should clean the glass plates with wax solution or French chalk. Possibly the prints had not dried completely when attempts were made to strip them.

**COPYING.**—I have an article of five or six pages in a book which I wish to copy out. Is there any method of transferring it out on

to paper by contact in any way? I want about half a dozen copies and do not care to write it out, it would take too long.—TRANSFERRING.

The most practical method (photographic) is to make negatives, on photo-mechanical plates, and take off bromide or gaslight prints. In our own case we should get a typing office to make two copies, and simultaneously two "carbon" duplicates from each.

**CAMERA OBSCURA.**—Could you kindly give me any information as to the cost (and where obtainable) of a camera obscura? Do you think it would be a paying investment, say at a seaside resort?—SPECULATOR.

We doubt if a camera obscura is regularly made by any firm now. You can occasionally see one advertised in our "Apparatus for Sale and Wanted" column. We believe that a year or two ago Messrs. Penrose and Co., 109, Farrington Road, used to list apparatus of this kind, and you might drop them a line. We can pronounce no opinion as to the paying nature of the business.

**STRIPPING POSTCARDS.**—I have lately tried some new postcards, but find I have trouble in getting same off glass. I use formalin, 3 ozs. to 40 water, and clean glass with benzene and spermaceti. I have enclosed a card, which, although I dried first, I had trouble in getting off. Should be pleased if you can say if cards are at fault.—W. L.

It is scarcely likely that the cards are to blame. Generally 5 per cent. alum solution for ten minutes is sufficient to bring the cards into good condition for stripping, and the results are usually more certain than with formalin. We can only advise you to try again with a good plate-glass. See answer to "Glazing P.O.P."

**L. R. C.**—"Photo-Revue," 118, Rue d'Assas, Paris. The rates will be sent to you on application to the above address.

**SELF-TONING PAPERS.**—Herewith find five self-toning prints, very badly stained. I should esteem it a favour if you will kindly let me know, through your *BRITISH JOURNAL OF PHOTOGRAPHY*, what the spots are and the cause of same, if you think its in the manufacture of the paper or manipulation? They were all fixed in a 10 per cent. hypo bath for ten minutes, and then washed and dried in the usual way.—E. HIGGS.

Quite impossible to answer your questions definitely without more details. A prolific cause of spots on self-toning papers is the use of impure blotting-paper for drying purposes. You can take it for granted that there is a lack of cleanliness somewhere in the treatment of the prints. You should state paper used, and give full particulars of treatment to enable us to suggest the source of the trouble.

**MOUNTING ENAMELLED PRINTS.**—Our business requires us to use a number of enamelled P.O.P. prints, and we want a good means of mounting same. Could you possibly give us a formula for making a solution that we can apply to the backs of the prints whilst they are on the enamel glasses that we could use. We know the difficulty is these solutions are as a rule waterproof, and the prints are wet when put on the glasses, but amongst your numerous correspondents we should like to know if you have found one who has overcome this difficulty. We should also like a good formula for backing dry prints for this purpose. We have one we make, but it is not always successful. If you can enlighten us in any way we should esteem it a favour.—P. H. T.

We doubt if you would find the dry-mounting method too expensive if you have much mounting to do, as the saving in time must be considerable over that taken by other methods. Why not try the secotine method described in our issue of November 29, 1907, p. 911.

**GLOUCESTER.**—We should say there is not much commercial value in a process giving a tone similar to that sent, but there would be for one giving a good sepia or warm brown. There are one or two preparations on the market in the way of warm-tone gaslight-paper developers. Messrs. Griffins make one.

**FLASHLIGHT.**—I have a flash-lamp in which percussion caps are used, but there is a danger of missing fire if the cap is not exactly central, and it is a nagging job to fit the cap. Could I make some caps with a much larger (spread out) charge, so that the chance of not firing would be lessened? 1. What would be a suitable

mixture? 2. Could I make the paper inflammable, like gun-cotton, so that the sparks of percussion would ignite it? Saltpetre burns rather slowly. I ask because the powder I use (Agfa) seems to be harder to set fire to than others, and will not always light from a spark, but once alight the difference in light and freedom from smoke is enormous.—D. B.

1. We cannot recommend you to attempt the manufacture of percussion caps, the fulminates employed are too dangerous to inexperienced hands. Possibly you can obtain larger caps by writing to the manufacturers. 2. Gun-cotton or any similar nitrated compound would certainly explode if ignited with a percussion cap, so we cannot recommend you to try this expedient. A good deal depends on the way in which you arrange powder and cap. If you find out the best way and keep to it you should have no misfires.

**CARBON.**—What is required for the work is a hot rolling-press, with the roller made only sufficiently warm to soften the moistened gelatine, so as to make it adhesive. The roller must not be made hot enough to melt the indiarubber. We do not think you will be very successful with a laundry iron, unless the pictures are small.

**F. HOLLOWAY.**—Thank you. We are using the paragraph.

**AUTOCHROMES.**—(1) Is the Gravier method of developing Autochromes suitable for lantern slides? I gather that unaltered bromide is left in the film. If so, I suppose the slides would be denser than those made in the ordinary way. (2) I suppose M. Gravier's ingenious cover for daylight development is not commercially obtainable.

(1) There is the silver bromide, but in the one or two examples we have made we have not noticed any marked additional density. (2) As mentioned in our issue of January 10, p. 34, from M. Mathieu, 62, Rue des Marais, Paris, price 10fr. 75c. (3) We should say any metal tank is unsuitable for the acid permanganate solution.

**C. W. and Others.**—In our next.

**OPERATOR.**—We should say the business is a genuine one, and not dear at the price. Cannot you arrange deferred payment for the amount by which you differ from the owner?

**STEEL ENGRAVING.**—Is it possible to get a steel engraving done from a cabinet photograph of group, two persons, the size to be 25 x 21 inches? The address of firm doing such work and cost of same would oblige. What kind of enlargement would most resemble a steel engraving?—P. J. S.

What you require is a photogravure plate, which is a copper plate faced with steel. The Autotype Company, the Art Reproduction Co., Plough Court, Fetter Lane, and others, produce such plates in England. The price will depend upon the amount of hand-work there is to be on the plate. Those who do the work will give you a quotation for it. No enlargement has the quality of a steel engraving, but the use of fine silk or the Autotype Co.'s texture films might give you a somewhat similar effect.

**T. BEDWELL.**—So far as we are aware, the paper is not now on the market. The company that exploited it some time ago is now, we think, in course of liquidation.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

the exhibition of photographs by members of the Professional Photographers' Association opened yesterday at the house of the British Journal. An article apropos of the exhibition by Mr. C. Tilney appears on page 99.

r. George Davison, it is announced, is retiring from business and the managing directorship of Kodak, Ltd. is to be in the hands of Mr. W. S. Gifford. (P. 108.)

agar-agar Emulsions.—Messrs. Cooper and Nuttall refer to some of the points raised in our article of last week. (P. 109.)

glazing P.O.P.—We mention a probable cause of recent failures in stripping P.O.P. (p. 97). A correspondent gives a method, which has been used with success, on page 110.

l printing was the subject of a demonstration at the Royal Photographic Society on Tuesday last by Mr. John H. Gear. (P. 107.)

t the Hull Society a demonstration of odourless sulphide substitute (thiomolybdate) in the sulphide toning of bromides was given. (P. 107.)

continuation of articles on profitable applications of carbon printing we give directions for the production of photographs on various cases and similar articles. (P. 98.)

## "COLOUR-PHOTOGRAPHY" SUPPLEMENT.

French worker, M. Charles Simmen, has recommended an amide-developer for the Autochrome process to be used in a weak solution in light in which the plates can be inspected. (P. 9.)

Le Roy recommends correcting the bluish tinge of an underexposed Autochrome with a weak bath of yellow dye. (P. 11.)

suggested use of Autochromes is in the sale of pictures, porcelains or other articles of value which cannot be shown to a purchaser at a distance. (P. 10.)

Several accessories for use in the Autochrome process have been introduced on the market. (P. 15.)

Green-plate Processes.—We give the chief part of the text of a recent lecture by Dr. C. E. K. Mees before the Society of Arts. (P. 12.)

r. Lehmann's observations on the Purkinje phenomenon in photographic plates appear on page 11.

## EX CATHEDRA.

### Glazing Prints.

During the past few weeks we have received such a large number of complaints with regard to failures in glazing prints, that it appears probable that the weather has something to do with the matter. The universal complaint is that the prints strip from the glass with difficulty and show various spots and markings. Many of our correspondents are careful workers, familiar with all the necessary details of preparing glass and prints, therefore it seems certain that the trouble is due, not to careless workmanship, but to some cause that they have not suspected, and, therefore, could not guard against. The most probable explanation seems to be that due allowance is not made for the dampness of the atmosphere, which has been excessive of late. If the gelatine is not perfectly dry, it, obviously, is not likely to retain a perfect gloss when stripped from the glass or glazing slab employed, and there have been many days this winter in which the drying of gelatine has been practically impossible without the adoption of special measures. Heat is probably the most commonly used drying agent, but this is somewhat risky with gelatine that is in an unusually moist condition, and it is quite possible that undue heating has been the cause of some of the mishaps brought to our notice. A safer method would be the employment of a drying cupboard or box, fitted up to serve as a desiccator. A dish of fused calcium chloride, or of sulphuric acid, would ensure the drying at a fairly rapid rate of any prints put into the same enclosure, and a small cupboard, or large box with well-fitting lid, could easily be utilised for the purpose. This should prove a cure if the trouble is due to the cause we suggest, while if the expedient fails, it would show pretty clearly that some cause other than damp air should be looked for. The experiment, therefore, seems to be well worth a trial.

\* \* \*

### Paper Prints from Autochromes

Mr. R. Raymond suggests in the current number of "La Photographie des Couleurs" a process of printing Autochromes on bichromated gelatine. A sheet of celluloid or mica is bound up with an Autochrome, so that it will not shift. It is then coated with bichromated gelatine, dried and exposed to light through the Autochrome and a colour filter corresponding to one of the colours of the starch grains. It is then washed or developed and inked up with a transparent greasy ink corresponding in colour to the filter. This operation is repeated three times, a different colour filter and a different ink being used each time. The result will be a complete colour-print, all except for the blacks, and these are produced by coating the picture with

a silver halide emulsion, exposing to light, and reversing as in the original plate. The print is then stripped and bound up, and one has a perfect reproduction of the Autochrome. The suggestion is ingenious, but, unfortunately, there are one or two points which the author does not make clear. The sensitiveness of bichromated gelatine to the spectrum extends in a gentle curve from the ultra-violet to a maximum at F in the bright blue, and then drops suddenly to nil at F $\frac{1}{2}$ E. How is one to render it sensitive to the rest of the spectrum, or to those colours transmitted by the green and red starch grains?

#### —And an Obstacle.

It is true that Calmels and Clerc ("B.J.," June 16, 1905, p. 472) state that bichromated gelatine could be colour-sensitised by the addition of erythrosine and other fluorescine compounds; but this has been denied by Tschörner ("B.J.," September 22, 1905, p. 755) and Neuhauss ("B.J.," December 8, 1905, p. 969), so that we are not much advanced. Beyond this, however, if the light is to act on the fourth coating of the silver halide emulsion through the coloured starch grains, it is obvious that it must be panchromatised. The author's statement, therefore, that his process will do away with all the difficulties of the old methods of printing in colours, "elle est à la portée de tous," or, *vulgo*, "any fool can do it," may be true, but it looks as though it replaces them by others which are not less troublesome, the least of which is, of course, the manufacture and coating of a panchromatic emulsion.

**"Tele"-words.** The processes of telegraphic transmission of pictorial matter which Dr. Korn and others have originated have led to the confusing use of the word "telephotography" for two totally different operations. But worse is yet to come, if we may judge from recent instances in the daily Press, where the prefix "tele" is employed unmistakably as implying wireless control of electric installations. Thus we find a London morning paper writing "Telemechanism—a new word for the wireless transmission of electric power." "Telephoto," like "aerography," has already two distinct significances, and is now to have a third bestowed upon it by hasty writers in the lay Press.

### PROFITABLE FORMS OF CARBON PRINTING.

#### III.\*

In two previous articles we have described methods by which the carbon process may be turned to profitable account by professional photographers. They were but slight departures from the ordinary method of working the process. One may now refer to still another application of the process for which there is, perhaps, less demand, but which, nevertheless, fairly comes within the scope of the present series of articles—we refer to the production of photographs on watch cases, cigar and cigarette cases, and similar articles. Instructions for working this process with the aid of a silver print-out process appeared in the JOURNAL some years ago, but we are now able to give a more satisfactory procedure in which carbon is the only process employed, an advance as regards certainty of permanence in the result. In describing the *modus operandi* we shall assume, as in the two previous articles, that the reader has an acquaintance with the practical working of carbon.

Let us suppose, for example, that we have to supply a customer with a portrait on the inner dome of a watch case. The work may be done either by the single or the

double transfer process, for both yield equally good results. It goes without saying that if the former method be adopted the negative must be a reversed one—that is, as regards right and left. In the first place, the inner dome of gold or silver must be removed from the watch by taking out the pin of the hinge. This the photographer had better get a neighbouring watchmaker to do for him, or, better still, the owner should be asked to get it done and deliver only the dome to be dealt with.

We shall for the nonce assume that single transfer is the method to be used, in which case the dome, after being cleaned with soap and water and thoroughly rinsing, coated with the substance given in the previous article, viz.:—

Nelson's No. 1 gelatine .....	1 oz.
Water .....	20 ozs.
Chrome alum, dissolved in 2 ozs. water...	20 grs.

This should be applied with a flat camel-hair brush as allowed to dry. In taking the portrait it should be made rather small, as one of large size in proportion to that of the case would have a vulgar appearance, and, moreover, would not be so easy to manipulate on a more or less convex surface. The negative should be masked to an oval, or circle, of suitable size, so that it prints with a clean margin, or it may be vignettted, according to taste. The most suitable colour-tissue is, for gold a warm blue, and for silver a warm brown. The tissue is printed in the usual way, but before it is mounted on the metal for development it should be trimmed down to but a little larger than the masked oval or circle. The reason for this is that the smaller the tissue, the easier it is to secure perfect contact at the edges on a slightly convex plate. The coated metal is placed in cold water for a few minutes for the substratum to get well saturated. The print tissue is then immersed, the two brought in contact, and then squeegeed together. The best squeegee for the present purpose is the finger. The tissue, which should be softened rather more than usual, is placed in position, held by the finger and thumb of the left hand while it is firmly stroked from centre to edges by a finger of the right hand, so as to ensure good contact. The back is then closely blotted off with blotting-paper.

After resting the usual time, the picture is developed in the ordinary way, alumed, and allowed to dry. If it is a good plan, in the development, soon after the paper backing has been stripped off to rub away carefully with the finger the coating at the edges of the print, for that is done at an early stage of the development a perfectly white margin is ensured in the finished picture. When dry the picture is varnished with a very hard varnish. The best for the purpose is the Zapon enamel No. 103 $\frac{1}{2}$ , sold by the Crane Chemical Company, of Birmingham. It is applied with a soft camel-hair brush. This, it may be mentioned, is a varnish specially made for metals—gold, silver and gilt.

In the above we have assumed the single transfer method to be employed, but the double is equally applicable. In this case the metal is coated with substratum for the double transfer method of producing pictures on porcelain plaques, viz.:—

Nelson's No. 1 gelatine .....	1 oz.
Water .....	20 ozs.
Chrome alum, dissolved in 2 ozs. water...	12 grs.

In this case the print is developed on flexible support in the usual manner, and, after being alumed and allowed to dry, is ready for transferring to the metal. The picture on its support is then soaked for a quarter of an hour or so in cold water to soften it. The gelatinised metal is then put into warm water about 85 to 90 deg. Fahr., until

\* "B.J.," January 17 and 24.

coating on the metal has acquired a distinctly slimy, the two are then brought together and pressed into mate contact as just described. When dry, the support is stripped off, and the picture is then ready for finishing. If the surface on which the picture is to be very convex, or departs much from the flat or lunette, difficulty may be experienced with the ordinary flexible support, by reason of its thickness and rigidity, in getting successful transfer. In such cases it is best to employ an indiarubber support as described in the *JOURNAL* January 17, 1907, for pictures on Japanese papers, using a very thin paper, such as "Bank Post," for the support.

In an alternative plan, when very convex surfaces have to be dealt with, is to develop the picture on a collodion support. A glass plate, previously waxed or treated with French chalk, is coated with an extra thick enamelling

collodion. When that has thoroughly set, the plate is put into cold water until all apparent greasiness is removed. The exposed tissue is squeezed on this, developed, and alumed as usual and allowed to dry. The film is then stripped off the glass and floated in position on to the softened substratum on the metal and then smoothed in contact with the finger, lightly used, or with a camel-hair brush. When dry the collodion can be dissolved off with a mixture of ether and alcohol. The picture is then varnished as before. It is a good plan, before stripping the film from the glass, to trim the picture to size. This is best done with a wheel cutter, as then the edges will not be ragged, as they might be if a penknife were used.

What has been said about the production of photographs on watch cases applies equally well to other metal articles, such as cigarette cases, match-boxes, and other articles of which photographers might make a profitable feature.

## THE SECOND EXHIBITION OF THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

YESTERDAY the doors of the "Little Galleries" in Wellington Street were opened to the public for a second exhibition of the work of the professional photographer. It would be a good thing indeed if the "lay" public, or the men and women in the street, could be induced to crowd in. They would at least have the advantage of a select and bird's-eye view of what is being shown in the way of portrait photography: a better view than can be obtained by promiscuous glances into the same old series of show cases with which their daily round brings them face to face.

The Association does not lay itself out for the entertainment of the public, however. Its object is primarily to allow professional men to see what others of the craft are doing, and that means to establish a bond between them which shall be of the same time educational and commercially advantageous.

Naturally enough only firms who are members of the Association are invited to exhibit, and this fact, of course, involves the exclusion of several having world-wide reputations. But these, it is hoped, will, in the course of time, rank themselves with the leading members to the mutual benefit of all.

There is no moment's doubt that the present show is an advance artistically upon the last. Nevertheless, it cannot be denied that old-time principles, methods, and traditions seem as firmly fixed as ever. There is evidence that the work of a firm is very largely controlled by its studio paraphernalia. An operator gets accustomed, it may be, to placing his sitter always in the same spot; always in the same light; backed always by the same range of backgrounds; supported always by the same set of accessories. Possibly the operator would be a little more open to change if these factors were thoroughly changed. But it remains to be proved whether this slight "throwing out" would be an ultimate advantage, inasmuch as it would introduce new conditions, and therefore new ideas and new resources. These would perhaps arrive the look of freshness which is undoubtedly lacking in almost all professional work.

Whatever are the sins of the amateur, and they are many, in the end, yet he has with them all, and by reason of them all, a freshness of attack which is sometimes captivating. He is not fettered by a studio routine, but is for ever being faced with new problems called up by the ever-shifting conditions of his

professional scores in the matter of certainty of result; economy of material and labour, and, having all his procedure in his finger-tips, his technique and execution are assured. But, unfortunately, his results are no less assured—that is to say, they are as like each other as slight differences in scale and

mounting will permit. If there is any suggestion of stagnation in his work, it is to be found at this point.

Another matter suggested by the present exhibition is that of the banal smoothness due to retouching. Porcelain faces are still in demand, it would seem. One would have thought that the public might have been educated before this to see that mere smoothness for smoothness' sake is unalloyed vulgarity. People are not all so crassly vain and ignorant as to think that a portrait of themselves without a spot or wrinkle—to say nothing of modelling due to the presence of facial muscles of which nobody need be ashamed—could be believed in by their friends. It is impossible that such people can believe in them themselves. Who, then, does believe in them? An amateur's portrait was recently greeted by the following remark from the sitter:—"Well, that's the first photograph of myself that I have ever had taken that did not look smug, and it's the only one I ever liked." That criticism is the key to a very large portion of the complaints heard so often from professional men. Not everybody wants a so-called "pretty picture": a good few want what they ask for—a likeness. Likeness does not depend upon posing, upon light and shade, upon the grand swing of the train of a dress, or upon any of the matters so uppermost in the professional operator's mind. It depends upon the actual reproduction of the forms and shadows thrown by the modelling of the facial muscles. To sweep these all away, or to soften off their crispness of edge into a nebulosity that can represent nothing, is to place portraiture more than three centuries back, when Queen Elizabeth is said to have commanded the removal of the shadow by the side of her nose, a truthful detail which the painter of advanced notions had had the temerity to set upon his canvas.

This matter of retouching constitutes the great gulf between the professional and the amateur. The latter knows that if all is satisfactory before exposure is made it is madness to make graphic alteration of the resulting image. He may control the key of tone, he may take unwarrantable liberties in the presentment as a whole, but he does not tinker with the drawing and modelling of the features.

It is curious that such conventional ideas should survive where in other ways there is so much that is smart, clever, tasteful, and artistic. Effects of light seem to have been thoroughly explored, and in posing figures it is difficult to imagine anything graceful that has not already been tried. Indeed, in these matters we are pretty near the point of exhaustion, which accounts perhaps for the fact that resource and invention are now largely in the direction of the mount.

In the present show the mounts are very varied, and one must be thankful for the harmonious touch supplied by the promoters of the exhibition in further mounting every picture in the *passee-partout* manner with gold bindings. Homogeneity is thus preserved for the mass, whilst each separate mounting can be seen as easily as ever.

One of the most taking styles is the adoption of a frame design after the manner of an old copper-engraved portrait. It is, of course, quite out of keeping with the texture of a photograph; but one has to get used to such improprieties in commercial art, and purity in such affairs is at a low ebb everywhere in these days. The contrast involved between the line engraving texture and the tonal texture of a print is pleasing, at any rate. The American or multiple mounting seems so far to have no attraction for the professional man.

A detailed criticism of the exhibits would be at once unprofitable and invidious. But it may be worth while to mention the prints that strike one as being attractive in each contributor's selection. Messrs. W. and D. Downey send work that is very distinctive in style. It is straightforward, relying alone upon its quiet undemonstrative excellence. An ecclesiastic sitting at a writing table, a portrait of Miss Gabrielle Ray in Japanese costume, a view of the same lady's unrobed back, and a delicate vignette profile wherein the hat is an artistic aid; these will be the most admired of the group perhaps.

Messrs. Turner and Drinkwater work in a smaller scale, and have devised a narrow border close to the print which appears to be simply a matter of exposure of the margin of the paper. Its edges are softened. Their best-composed portrait is that of a lady holding a little boy who sits on the back of a tall chair. This is a very taking example.

A varied selection is sent by Mr. G. C. Beresford. 'One or two large heads, the prints of which are trimmed close, are particularly good, especially that which may be the portrait of Earl Spencer. A most unconventional but charmingly natural pose of a young girl who leans over to her right side upon her straightened arm, offers endless suggestions to a resourceful mind. The same firm have a head of the "heroic" type swathed in a tightly wrapped head-dress. It is very effective and remarkably well schemed; but it is surely not submitted as a piece of professional portraiture.

Messrs. Drummond, Young, and Watson send what is obviously an imitation of a famous Whistler portrait, the "Miss Alexander." She stands with hat in hand, with somewhat the same pose, and even a screen as background. It is very questionable whether anything is gained by these fancies. Photography is powerless before the greatest characteristic of this work of Whistler's, which is its colour and by no means the mere pose of the figure. A much more satisfactory work is the same firm's subject of a lady in profile at three-quarter length dressed in Early Victorian style, and the whole very tastefully tinted.

Mr. Henry S. Spink's work is largely confined to portraits of

Mr. DOUGLAS J. CARNEGIE, an occasional contributor to our pages, has been lecturing at Newcastle-on-Tyne, and some interesting particulars of his career are given in the current issue of "Weekly Notes and Programme," a publication which deals with matters scientific and otherwise in that district. Mr. Carnegie, who is well-known for his invention, in conjunction with Mr. C. Welborne Piper, of the chromium intensifier, received his early education at Staveley Grammar-school and Epsom College. From the latter place he qualified for an Exhibition Scholarship in chemistry at the London University, and gained an entrance science scholarship at Gonville and Caius College, Cambridge. He secured a double-first in parts 1 and 2 Natural Science Tripos, 1884-1886, and became assistant lecturer and demonstrator in the chemical laboratory of Caius College (1884-1889). From 1890-1893 he was Professor of Chemistry in Colorado College, U.S.A., and from 1893 to 1896

children. They are also slightly tinted. Mr. Spink has a knack of getting charming babies as sitters, and of photographing them at their best. He has further made a happy choice of elaborate design in the band of ornament that sets off his attractive pictures.

Mr. Gill, of Colchester, in his delicate portraits appears to be using the property balustrade more than hitherto. Photographers must recollect his many charming portrait studies taken against genuine panelled backgrounds and window niches.

Mr. Ralph Robinson (H. P. Robinson and Co.) has already a high reputation for children's portraits. Those he sends here are as captivating as ever, especially the oval that contains a mother holding her little one.

Sarony, of Scarborough, contributes some excellent and bold work, the best example being a fine head of a young lady, where the treatment of the loosely dressed hair is effective. Other heads of women and children are also strongly and effectively given.

Mr. Moffat, Edinburgh, displays great taste in the portrait of a lady in wedding dress, photographed in the hall of her fathers, where the introduction of a screen successfully quietens the background, and yet allows the hall to be significantly apparent. A group of a musical family is also noteworthy in view of the difficulty of perfect spontaneity in such a subject.

Capital expression is secured by Miss Lizzie Caswall-Smith, a child holding its hand to its mouth, and in another half-subject, where the pleasing tones of the flesh against the whiteness of the robes is artistically felt.

Messrs. Alfred Ellis and Walery make a great feature of the relief afforded to a figure by its background. Where the shape—or the "pattern," as artists say—is good in design, a few decorative breadth results. Here a girl eating grapes makes a dark shape against the background; the young lady with her foot upon the stairs makes a white shape.

The specimens from Mendelssohn are good in technique; but they do not appear to be finer than the great reputation of the firm would lead one to expect. They are portraits of aristocratic notabilities for the most part, and all have dignity of character.

Of the late Mr. Martin Jacolette's most attractive contributions the best is a Court-dress piece with a particularly nice background.

Mr. Lancaster, of Tunbridge Wells, scores with a portrait of an old man, which has excellent character and is capitally lit.

From the same town also are some children groups by Mr. Gordon Chase. Children also form the staple of Messrs. Hugh and Mullins's selection, and Mr. E. C. Ballard includes two interiors and a landscape.

Excellent equestrian studies, sent by Mr. Tom Reveley, complete the display.

It may be stated that all exhibitors were asked to submit eight photographs, from which six were selected for exhibition.

F. C. TILNEY.

was science master of Ley's School, Cambridge. He is an Extension Lecturer for the Universities of London and Cambridge, and was for some time research chemist to the Cambridge Colour Works, Loughton.

MR. FREDERIC T. CORKETT informs us that owing to the rapid expansion of his business, and in consequence of his appointment as Art Editor to the Fine Arts Publishing Co., Ltd., he has found it necessary to remove from the Studio of Design, 2, 3 and 4, Charing Cross House, 29A, Charing Cross Road, W.C., from which address all the Burlington Art Miniatures will in future be published. All communications therefore relating to the Miniature and Commercial sections of the Fine Arts Company's business should, on and after February 3, be addressed to Mr. Corkett at the head office of the Company, Charing Cross House, as above.

ORTHOCHROMATISM BY BATHING.—A SENSITOMETRIC STUDY.

THE following is the full text of a further communication in the series of researches by Mr. R. J. Wallace, of the Yerkes Observatory, appearing as "Studies in Sensitometry." The same author's first published experiments on a system of daylight sensitometry appeared last year, and were reprinted in our columns from proofs specially prepared, as was the present paper, by Mr. Wallace, for "The British Journal of Photography." Our acknowledgments are therefore equally due to Mr. Wallace and to the "Astrophysical Journal," in which the papers have first appeared.—Eds., "B.J."]

The Influence of Temperature of the Dye-Bath.

The influence of the temperature of the sensitising bath upon the rate was studied by making up bath 124, which was cooled by pans of ice to a temperature of 12deg. C., and in which were then bathed two plates for three minutes, and subsequently washed in alcohol at similar temperature for thirty seconds. The temperature of the bath was then raised by seven separate stages to 30deg. C., two plates being bathed at each step in the rise. All plates were then rapidly dried at the same temperature. Exposure of each plate to the spectrum series of a constant acetylene flame showed a very interesting and clearly defined difference, which was borne out by a second series bathed on the following day and exposed to diffused daylight. The following are the measurements of the principal plates in the series:—

Temperature.	Mean Density.			$\chi = \frac{\beta}{\lambda 6500}$
	At $\lambda$ 6500	At $\lambda$ 5900	At $\lambda$ 4300	
0 .....	1.3500	1.2440	2.3128	1.71
10 .....	2.1370	1.8160	2.2502	1.05
20 .....	1.8660	1.5206	1.7686	0.95
30, plate melted.....				

and their accompanying curves (Fig. 2).

It therefore follows from the foregoing results that an increase in the temperature of the dye-bath exercises a beneficial effect upon the relative chromatic sensitiveness of this plate. This effect has been confirmed in many other instances throughout the course of the investigation. The temperature of the bath is therefore kept constant at 23deg. C. Referring to the plates of different makes which have also been experimented with in this regard, it results that, although the effect is not identical with each, it yet appears to be uniformly certain with the Seed "27."

Results with the Various Dye Sensitisers.

The principal results may now be briefly considered as follows:—  
**Pinacyanol.**—A plate bathed in an aqueous solution of this dye and washed in water shows a strong sensitiveness to the spectrum from  $\lambda$  3,300-7,000, and with increased exposure to beyond  $\lambda$  7,200, with two distinct maxima in the red and green at  $\lambda$  5,270-5,800, and  $\lambda$  6,160-6,870. The addition of ammonia to the bath increases the red sensitiveness to a considerable degree, and this increase is proportional to the amount of ammonia added. The introduction of

ethyl alcohol to the dye-bath, and omission of the subsequent washing, results in a distinctly greater action from  $\lambda$  5,270-5,890, while the general effect upon the sensitiveness from  $\lambda$  5,270-6,580 is shown by a decided increase in relative chromatic effect. A subsequent rinse in alcohol after bathing shows a still further improvement.<sup>16</sup>  
Variation in the amount of dyestuff entering into the bathing solution was experimented upon in amounts varying from thirty minims to ninety minims in steps of ten minims. The greatest sensitising action upon the "27" plate was found to follow when the amount of dye was 1-68,000th to 1-70,000th, which is in close agreement with the experimental results of Mees and Sheppard.<sup>17</sup>  
Fig. 3 shows the curve of this type-plate, and illustrates the advantageous results following the addition of, and washing with, alcohol.

Fig. 3.

The reduction in speed from the "27" is 0.19.

In obtaining the  $\chi$  value for all of the following plates ( $\frac{\beta}{\lambda_n} = \chi$ ,  $\lambda$  4100  $\approx \beta$ , while  $n = \lambda$  5100, 5500, 5900, 6300, and 6800 respectively.

$\chi$ FOR PINACYANOL BATHED.					
Type \ $\lambda$	6800	6300	5900	5500	5100
1.11e.....	3.47	2.34	2.15	1.75	1.38
1.4e.....	5.79	3.76	3.25	2.01	1.53

**Pinaverdol.**—This dye in dilute alcohol bath sensitises for the green and orange-red of the spectrum extending to about  $\lambda$  6,400 (and with increased exposure to  $\lambda$  6,700), with two broad distinct maxima near  $\lambda$  5,900 and  $\lambda$  5,300. The best result from the use of this dye was obtained with a bath of the following constitution:—

Pinaverdol, 1 : 1,000 ..... 60 minims  
Methyl alcohol ..... 3 oz.  
Water ..... 4 oz.  
Ammonia ..... 60 minims.

Time of immersion, three minutes—no washing. Speed difference = 0.60. See 2.9f, Fig. 4.

At $\lambda =$ 6,300	5,900	5,500	5,100
$\chi =$ 5.73	1.79	1.75	1.31

**Homocol.**—This is a particularly interesting sensitiser for the green on gelatino-silver-bromide, embracing the entire region from  $\lambda$  4,860-5,460, and when made up with dilute ethyl-alcohol bath followed by alcohol washing gives a plate working with exceptional clearness. Its action is very similar to pinaverdol, although with equal exposure it does not sensitise so far into the red. As a sensi-

<sup>16</sup> The introduction of alcohol to the dye bath was published by Dr. E. König, who however treated the plate to a subsequent washing in water. *Photo. Korr.*, September 1905, p. 406.  
<sup>17</sup> *Theory of the Photographic Process*, p. 327.

tiser for the blue-green this dye has no equal (see Fig. 4, curve 4.9f)<sup>18</sup>. Speed difference = 0.61.

At $\lambda = 6,300$	5,900	5,500	5,100
$\chi = 5.20$	1.97	1.60	1.17

**Pinachrome.**—In dilute ethyl-alcohol plus ammonia bath this dye sensitises for the yellow-green and orange and shows definitely the  $\alpha$  and  $\beta$  bands characteristic of cyanin<sup>19</sup>. With normal exposure to

Fig. 4.

the spectrum the sensitiveness extends to  $\lambda$  6,300, but can be forced to beyond  $\lambda$  6,500 (Fig. 5). Speed difference = 0.36.

At $\lambda = 6,300$	5,900	5,500	5,100
$\chi = 25.7$	2.01	1.68	1.83

**Pinacyanol+pinaverdol.**—These two dyes in combination result in a very good plate in which the characteristic pinacyanol gap in the blue-green is very greatly benefited.  $\chi$  values for the various posi-

(3.11e.)

Fig. 5.

tions are given in Table A. The gradation values in this plate remain similar to the unbathed "27." Speed dif.=0.32.

**Pinacyanol+homocol** also forms a good combination, and one which has been recommended by Monpillard<sup>20</sup>. When made up in dilute ethyl-alcohol bath without ammonia the action throughout the red and green, although fairly even, is yet weak when compared with that in the blue-violet. The introduction of ammonia, however, shows a steady gain in the red and green sensitiveness as the amount is increased. (The same effect is noticeable as the bathing-time is increased.) With normal exposure the sensitiveness extends slightly beyond B ( $\lambda$  6,870), while with increase in exposure it runs beyond  $\alpha$  ( $\lambda$  7,200). From the blue the chromatic sensitiveness falls off rather

<sup>18</sup> This curve is not in agreement with that published by Mees, Sheppard, and Newton (*Journ. Roy. Phot. Soc.*, 45, 266, July, 1905). The difference results from the use of a dilute alcohol dye bath in place of an aqueous. An aqueous (ammoniacal) bath gave a similar result up to  $\lambda$  4,500 to that obtained by these workers. The replacement of the ammonia by potassium carbonate (and other alkalies) as recommended by Dr. König (*Phot. Korr.*, September 1906, did not prove successful in the hands of the writer.

<sup>19</sup> The two absorption bands of cyanin have been termed respectively  $\alpha$  and  $\beta$  by von Hülb. The former lies near  $\lambda$  6900 while the latter is near  $\lambda$  5450. *Eder's Jahrbuch*, 1905, p. 183; also *Journ. Roy. Phot. Soc.*, 46, 133, 1906.

<sup>20</sup> *Bull. Soc. Franc. Phot.* (2), 22, 132, 1906.

abruptly and then pursues a fairly uniform curve, which shows two distinct maxima at  $\lambda$  5800 and  $\lambda$  6,400 respectively. Decrease in the amount of pinacyanol accentuates these maxima, the best result being obtained with a bath composed of

Pinacyanol (1 : 1,000)	60 minims.
Homocol	60 minims.
Alcohol (ethyl)	3 oz.
Ammonia	90 minims.
Water (distilled)	4 oz.

Another bath made up with the same proportionate amounts of dye, but containing a minimum quantity of water and excess of alcohol, shows a peculiar drop in the red sensitiveness, which ends at  $\lambda$  6,560 very abruptly, and with an exceedingly pronounced drop in the orange at  $\lambda$  6,100, both drops becoming more pronounced as the dyes are increased in amount. A "27" plate treated in this bath resembles very closely in action the Seed "panchromatic" (see Fig. 6). When made up in ammoniacal water bath the sensi-

Fig. 6.

tising action is very weak and unsatisfactory; this weakness is still more apparent when the plate is washed in water after staining, but shows a slight improvement when the washing is conducted with alcohol. Speed dif. = 0.74.

(To be continued.)

### THE KODAK COMPANY IN INDIA.

THE past few months have witnessed the first steps of an extensive scheme on the part of Kodak, Limited, to carry a knowledge of the simple methods of photography associated with the name of Kodak into every corner of the Indian Empire. The scheme is under the immediate care of Mr. Hedley M. Smith, and it is intended to give every large centre the benefit of an imposing exhibition, in which can be seen not only the light and compact daylight loading cameras, and the machines for daylight development introduced by the company, but a splendid array of the results in the shape of enlargements and contact prints.

In the Bombay Town Hall the public have already had an opportunity of seeing the possibilities of the Kodak in the hands of the amateur. To quote from "The Times of India," the collection brought together by the Kodak Company was "undoubtedly the finest photographic exhibition that has ever been got together in the country. . . . Beside the display of pictures, the organisers of the exhibition have also arranged a show of their latest patterns in apparatus, so that the visitor who is unacquainted with the all-daylight procedure may easily make himself familiar with the process, and at the same time make comparison with some of its fine results."

To the man or woman in India contemplating photography as a

astime, the Kodak idea appeals particularly strongly. The compactness of the apparatus and supplies and their independence of the dark-room win the traveller at once, and it is not surprising that to the very large proportion of the British military and civil population who are enthusiastic Kodak users may be added large numbers of India's native peoples.

That the present steps will consolidate and greatly extend the already large business carried on by Kodak, Limited, in India, may be regarded as a certainty. The field is a large one, and should yield gratifying returns under the skilful and thorough methods of exploitation which we may expect the Kodak Company to apply.

## Patent News.

*Process patents—applications and specifications—are treated in Photo Mechanical Notes."*

The following applications for Patents were received between January 20 and January 25:—

**CAMERAS.**—No. 1,323. Improvements in photographic cameras. Layman Magarry Sternbergh, Chancery Lane Station Chambers, London.

**FLEXIBLE SHEETS.**—No. 1,327. Improvements in apparatus for holding flexible sheets and the like. Kodak, Ltd., Chancery Lane Station Chambers, London, for Norman W. Carkhuff, United States.

**OPTICAL PROJECTION.**—No. 1,328. Improvements in optical projection apparatus. Kodak, Ltd., Chancery Lane Station Chambers, London, for William F. Folmer, United States.

**DEVELOPING.**—No. 1,329. Improvements in photographic developing and like apparatus. Kodak, Ltd., Chancery Lane Station Chambers, London, for Frederick W. Barnes and Milton B. Punnett, United States.

**SCREEN-PLATES.**—No. 1,372. Improvement in the manufacture of screen-plates for colour photography. Edward John Wall, Castlebar Works, Ealing, London.

**COIN-FREED APPARATUS.**—No. 1,422. Improvements in coin-freed photographic apparatus. René François Frédéric Roupnel, Birkbeck Bank Chambers, Southampton Buildings, London.

**PHOTO-TELEGRAPHY.**—No. 1,515. Improved apparatus for wireless transmission and transmission by wires of photographs, drawings, and the like. Ferdinand von Madaler, 61, Stanley Street, Battersea, London.

**PROJECTION.**—No. 1,568. New or improved apparatus or appliance for displaying images of natural or other objects on screens. George Heaton Dugard, 35, Temple Row, Birmingham.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**ROTARY GLAZING OF PRINTS.**—No. 1,157. 1907. This invention relates to machinery for preparing glass or other plates and squeegeeing into contact therewith photographic prints and the like for the purpose of finishing by glazing. The apparatus consists of a rigid framing, *a*, constructed of wood or metal, consisting of a pair of longitudinal members braced together parallel at any required distance apart. Each side member has an upper and a lower rail and, upon these, extending from one side member to the other is mounted a series of rollers in suitable bearings. The rollers are so mounted in pairs, an upper and a lower in each pair, the

Fig. 2.

axes of the lower ones being in fixed bearings, *b*, while those of the upper rollers are in bearings, *c*, capable of rising slightly under the restraint of springs pressing or pulling upon them. The number of rollers may be varied, but a suitable number is eleven pairs, viz.:—(1) A pair of hollow perforated metal rollers, covered with swansdown or the like and fed, through their hollow spindles, with a spirituous solution of wax from an overhead tank (not shown); (2) a pair of conveying rollers; (3 and 4) two pairs of polishing rollers (5) another pair of conveying rollers; (6 and 7) two further pairs of polishers; (8) a pair of conveying rollers; (9 and 10) two more pairs of polishing rollers set obliquely across the machine; and (11) a pair of squeegeeing rollers. A larger number of rollers are shown in the drawings, in which A and B are extra polishing rollers and

Fig. 1.

**PRINTING.**—No. 1,595. Improved apparatus and means for photographic printing. John Mills, 162, Waller Road, Queen's Road, New Cross, London.

**COPYING.**—No. 1,615. Apparatus for reproducing at a distance graphic documents (photographs, blocks, drawings, and the like). Edouard Belin, 6, Lord Street, Liverpool.

**FILMS.**—No. 1,689. Improvements in or relating to the production of sensitised surfaces or films for photographic purposes. William Hay Caldwell, 46, Lincoln's Inn Fields, London.

C and D are extra conveying rollers. About the extremities of the conveying rollers, rubber bands, *m*, are so placed that they act as narrow friction surfaces serving to carry the plates between the rollers and to support the plates by their edges only. The conveying, polishing, and squeegeeing rollers have the ends of their axes extended outside the main framing whereon to fit gears by which motion may be transmitted from one to another. The polishing rollers, excepting those enumerated as 9 and 10 above, are driven through spur gears, both upon rollers in two adjacent pairs being

geared at one end and both corresponding lower ones at the opposite ends, the four then being connected by a further pair of gears fitted to one upper and one lower roller respectively. Those polishing rollers, 9 and 10, which are set obliquely are driven independently by means of bolts running over pulleys on their axes. Instead of these rollers, the purpose of which is finally to polish the plates, six discs may be used so arranged that half their number act equally upon either sides of each plate. The discs rotate on vertical spindles in separate frames mounted upon the main framing so that their faces are presented to the surfaces of the glass plates passed between them. They are driven by means of a belt, or in any other convenient manner.

In use, an operator inserts each plate between the waxing rollers, 1, and impels it forward until it is partly taken by the first pair of conveying rollers, 2, succeeding the waxing rollers. Thence it is mechanically carried to the polishing rollers 3 and 4, the length of each plate being such that, before one end leaves the first pair of conveying rollers, the other is taken by the second pair of conveying rollers and so through the entire series. As each plate leaves the last conveying rollers and approaches the squeeze rollers 11, prints to be finished are laid wet by hand directly upon the upper surface of the plate, and upon endless travelling tapes *c* below for application to the reverse side. These tapes run over plain rollers *f*, *g*, *h*, so that they take an inclined position with the highest point on a level with the plane of the plate to which the prints are to be applied. The speed of the machine is regulated to suit the operators in attendance. Charles Rubie Neve, Belmont, Spencer Road, Wealdstone, Middlesex.

**CINEMATOGRAPH MECHANISM.**—No. 15,902. 1907. The invention consists in an automatic safety device rendering it possible to stop instantaneously the propagation of the burning of the strips of film employed in cinematographs. It comprises an automatic device consisting of strips of highly inflammable material which may be stronger than the film, and which on being ignited instantly close the outlets and inlets of the incombustible magazines in which the strip of film is unwound and wound respectively, and this immediately the strip has become ignited. In conjunction with the above is a mechanical device by means of which the orifices may be closed hermetically, at the same time cutting the strip of film at these points. Arcade Mallet, 18, Rue de Mogador, Paris.

**PLATE CINEMATOGRAPH.**—No. 20,863. 1907. The apparatus, which is illustrated in five drawings, consists of an outer casing, enclosing a lens, a movable box adapted to reciprocate across the focus of the lens, a series of photographic plates in the box, screw mechanism for presenting the plates serially and with descending motion before the lens, a transporter within the casing adapted to receive and remove the plates one by one, and an expandable receptacle adapted to receive and hold the plates. Robert Arthur Fauconnet, 36, Rue de Menilmontant, Paris.

**CINEMATOGRAPH-PHONOGRAPH.**—No. 4,429. 1907. The claim is for "an arrangement for simultaneously operating in synchronism several phonographs and cinematographs by the electro servo-motors described in the Patents Nos. 1686-07 and 3927-07, characterised by permitting the simultaneous operation of any number of phonographs and cinematographs and employing between the transmitters and the receivers a conductor of three wires only. Maurice Couade, 5, Rue Richemane, Paris.

**CINEMATOGRAPH-PHONOGRAPH.**—No. 206. 1907. The first of the four claims is for "the construction of the indicating apparatus for photographs and cinematographs operating synchronously, comprising a pinion driven through a flexible transmission connected at its other extremity with one of the parts of the cinematograph, this pinion meshing with a wheel fixed to the shaft of the differential, the ratio between this pinion and the wheel being variable in order to admit of the employment of cinematographic bands and photographic discs of different makes, and in which the number of pictures per revolution of the disc may vary. Leon Gaumont, 57, Rue Saint Roch, Paris.

The following complete specifications are open to public inspection before acceptance under the Patents Act, 1901:—

**CINEMATOGRAPHS.**—No. 562. Apparatus for moistening cinematographic bands or films and the like. Lertourné.

**SHUTTERS.**—No. 563. Shutters for cinematographs and the like. Lertourné.

**COIN-FREED APPARATUS.**—No. 1,422. Coin-freed photographic apparatus. Roupnel.

## New Trade Names.

**GUINEA GOLD.**—No. 296,897. Dyes (mineral), alkalies, anti-corrosives, chemical substances for use in photography, glue, mordants and saltpetre. W. H. S. Taylor and Co., Ltd., 42, Market Street, Wigan. October 9, 1907.

**GER-WEE.**—No. 297,145. Chemical substances used in manufacturing photography or philosophical research and anti-corrosives. Fritz Beindorff, trading as Gunther Wagner, 80, Milton Street, London, E.C., ink and colour maker. October 17, 1907.

**ARSOI.**—No. 298,629. Chemical substances used in manufacturing photography, or philosophical research and anti-corrosives, but not including chemical substances for dyeing furs, hair, hides, skins, and the like, and not including any goods of a like kind to chemical substances for dyeing furs, hair, hides, skins, and the like. Georges François Jaubert, 155, Boulevard Malesherbes, Paris, France. December 6, 1907.

**GONDOLA.**—No. 298,713. Chemical substances used in manufacturing photography, or philosophical research and anti-corrosives. P. Morris and Co. (Chester), 135, Foregate Street, Chester. December 10, 1907.

**ENOL.**—No. 298,869. Chemical substances used in photography. Kodak, Ltd., 57-61, Clerkenwell Road, London, E.C. December 14, 1907.

**LION.**—No. 296,646. Cinematograph films, bearing taken photographs, machines for taking and showing cinematograph pictures. George Howard Cricks and Harry Martin Sharp, trading as Cricks and Sharp, Ravensbury Lodge, London Road, Mitcham, London, S.W., cinematographers. September 28, 1907.

**"VESCA."**—No. 299,018. Photographic cameras and other photographic apparatus included in Class 8. The London Stereoscopic and Photographic Co., Ltd., 54, Cheapside, London, E.C., and 106 and 108, Regent Street, London, W. December 20, 1907.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Stripping Negatives.

The following method will be found useful (writes Mr. John Sterry in "Photography") with those negatives which are but of doubtful value, and only kept in case of some future need.

The following solution is prepared:—

Sat. sol. of potassium carbonate .....	2oz. (by measure)
Glycerine .....	1oz. "
Forty per cent. formalin.....	1oz. "
Tap water to .....	50oz. "

The film may be stripped by the use of potassium carbonate alone, but the above seems to be more satisfactory. After standing a little while the solution will become cloudy, and must either be allowed to settle and be decanted or filtered before use. The plates should be immersed in the solution for half an hour, then stood to drain a few moments and surface-dried with an old cambric handkerchief made into a pad. They are then to be set up to dry in a cool place, so that the drying may be comparatively slow and regular. They will appear to be dry long before they are so in reality, or in a satisfactory condition for stripping. In practice six hours has been found a good time, but if left twelve or more the certainty of stripping perfectly flat is greatly increased. When thus ready for stripping it is only necessary to cut round with a sharp knife about 1-16 in. or  $\frac{1}{4}$  in. from the edge of the plate; then, gently lifting one corner, the film will separate with ease and lie perfectly flat. It should be placed downwards on a flat surface for a little time before being stored away.

**SPEED NUMBERS.**—In reference to a recent "Ex Cathedra" note on "Plate Speed Numbers," we ought to point out that the numbers in both cases were those of orthochromatic plates. Moreover, it is perhaps due to Mr. Watkins to say that the reference was not to the list of speeds issued by his firm.

## New Apparatus, &c.

**"FOLDING POCKET KODAKS."**—The latest models of the No. 1 and No. 1A of these well-known Kodaks are once more embodiments of the policy of the Kodak Company never to rest satisfied with a type of camera, to whatever pitch of perfection it may have come. In these new models the rigid double finder hitherto fitted is replaced by a single finder, so mounted as to be easily adjustable for vertical and horizontal pictures.

The method of inserting the spools of film has also been simplified, a neat nickel pivot pin, which is pushed in or pulled out directly by finger and thumb, taking the place of the device formerly fitted. The camera thus acquires the undeniable advantage of being opened and extended for use by one movement only.

The No. 1 Folding Pocket Kodak gives  $3\frac{1}{2}$  by  $2\frac{1}{4}$  pictures, and costs 2s.; the No. 1A Folding Pocket Kodak gives  $4\frac{1}{4}$  by  $2\frac{1}{4}$  pictures, and costs £2 10s.; both carrying films for twelve exposures without re-loading, while loading is, of course, a purely daylight operation.

**"Swincam" Tripod.** Model C (Tourist) pattern. Made by William Butler, 20, Crosby Road, Southport.

When Mr. Butler allowed us to test his "Swincam" tripod some two years ago, we expressed an opinion of it which we are glad to hear endorsed by many purchasers. The camera so made, it may be remembered, is of the substantial build necessary for supporting a large stand camera in practically any position. The new pattern is now offered in order to provide a tripod suitable for amateur user, but offering practically the same range of adjustments possessed by the original pattern. It is of the telescopic type, and the universal movements of the head are secured by two ball-socket attachments held in any position, each by a

nut. The head itself is  $1\frac{1}{2}$  inches in diameter, and is fitted with English and Continental screws for attaching the camera,

either of which can be used at option. The length of the thread projecting above the top of the head-plate can be adjusted to suit different makes of cameras, or both screws can be removed and the hole formed in the centre of the head utilised for securing the camera by means of a T-headed screw, the links when placed at an angle to the legs affording space for handling the screw, and enlarging the base for the support of the camera.

The mechanical design of the apparatus is an excellent example of strength and convenience, and the rounded-off finish of the brass and aluminium work no small recommendation to the tripod. The total height at full extension is 4 ft. 2 in., whilst when closed the instrument measures 1 ft. 5 in. by  $1\frac{1}{2}$  in. over all. Its price is £1 1s., and for a further 5s. 6d. a neat leather sling case is supplied. It should be mentioned that Mr. Butler, who is an engineer holding a responsible post in the North of England, himself examines and adjusts each tripod before it is sent out, a guarantee, if any were needed, of the thorough workmanlike construction and finish of each instrument.

## New Materials.

**"Chromona" Green Toner.** Made by the White Band Chemical Company, Progress Works, South Croydon.

That there is a demand for a process of toning bromide or gas-light prints to a green colour is evident to us from the frequency with which a request for a formula is addressed to us. To such questioners we have usually recommended a green carbon tissue for the reason that we knew of no toning preparation which could be depended upon to do its work with sufficient certainty and rapidity. But we must now admit, after trying the solutions submitted to us by the White Band Co. that in their new "Chromona" green toner they have issued a preparation which acts most satisfactorily. It is supplied in two solutions, No. 1, blue, and No. 2, yellow, which, after dilution in each case with five times its volume of water, are mixed, and form the toning bath. That is to say, 2 drachms each of Nos. 1 and 2 are separately diluted to  $\frac{1}{2}$  ounces of water and mixed together. The 3 ounces of mixture are prescribed for four half-plate prints of average depth, a number which we have found it to tone fully. The process occupies about five minutes, and is followed easily on removing the print or pouring off the solution for a moment. The yellow toner masks the action to a slight extent, but if, after a rinse, the print is found not to be toned enough it can be put back and the process continued further. The yellow stains which covers the whole print is discharged in water in five or ten minutes, leaving absolutely pure high-lights. During this stage, as we have just said, the full green tone becomes visible.

In using the toner on a number of bromide prints we were unable to notice any loss of intensity worth mentioning. There may be a very slight reduction, but it is practically negligible. Certainly, a print which is of full proper strength is equally so after toning. The longer the toning action is continued the brighter the green produced, and it is in the production of a brilliant green that loss of intensity may be noticed. The less brilliant tones are, however, the most effective. The solution is suitable for all bromide paper, though not for every gas-light paper. It is equally applicable to freshly made prints and those which have been made some time. Among those which we have toned was one torn from a 1903 catalogue, and therefore at least four years of age. The new solution thus appears to us to be a bath deserving of recommendation, and likely to be of much use to professional photographers able to employ it in producing some new style of photograph by its means. As regards the permanence of the results, we have no means of speaking, but the makers have not issued it until after satisfying themselves on this point, and the activity with which the solution effects the change in the prints certainly suggests the thorough and direct conversion of the silver image. The toner is sold in two solutions, sufficient for several dozen half-plate prints, at 1s. 6d. We should add that we found the toner act satisfactorily in the case of a lantern slide.

**"Diachrome" Toning Solutions (Traube process).** Made by Perutz and Co., Munich, Germany.

We have, in past issues of the "B.J.," alluded to the so-named "Diachrome" process of dye-toning, worked out and patented by Dr. W. Traube, of Berlin, for both monochrome and three-colour

printing. The principle of the process consists in bleaching the image of a positive transparency on glass with a bichromate mixture containing iodine, thus converting it into silver iodide. On immersion in a suitable dye-bath, this iodide image combines with the colouring matter and forms a definite coloured image, the depth of which in the various gradations depends on the gradations of the original image. The image can be left at this stage with the silver iodide in it, or the latter can be dissolved out with a suitable bath of hypo, that is one containing, we believe, certain metallic salts. Our experience of the process, however, is limited to the former of these procedures, as none of the special hypo bath has yet reached us. Dr. Traube, however, has been good enough to send us a small supply of the materials which has sufficed to show us the very easy character of the process and the beautiful results given by it. The operations are not complicated. The transparency, after removal of hypo by washing, is bleached in the No. 1 solution. In the space of a couple of minutes it is bleached through to the back. It is then rinsed in plain water until clear of yellow stain, and then put to soak in the dye bath, made by dissolving the pellet in  $4\frac{1}{2}$  oz. of water, to which a drop or two of 80 per cent. acetic acid is added. Here the dye combines with the bleached image and at the same time stains the gelatine. All traces of the latter action, however, are removed by a short wash in running water. The high lights are left perfectly clear glass, and the image of a rich green or brown colour, according to the dye selected. The whole process occupies little over half an hour, in which time a fair number of lantern slides can be treated, since the process requires no control at any stage. The slide is fully bleached and fully stained, and the coloured image appears to be an equivalent in every way save colour of the black silver image which formed the slide at the start. The slides, it should be added, do not exhibit the same colours on projection which they do when examined by diffused light, except in the case of the two dyes specially prepared for projection.

So far as we can judge from our use of a small sample, the "Diachrome" process supplies a most easy and certain method of obtaining transparencies in brilliant colours. The very brilliance of these is perhaps a drawback since many subjects are unfitted for any such bright colour. But in all probability any degree of "saddening" of the dyes can be introduced and a mixture constituted which will give a colour just as nicely as the gum-bichromate or oil-worker can mix his pigments. This, however, is only conjecture on our part, a mere guess, which is perhaps father to the hope of bringing lantern slides into more exact correspondence with the methods of photographic printing. Certainly the "Diachrome" process should be tried by those who are dissatisfied with the all too few methods of producing warm tones on lantern slides.

"RUSKIN" MOUNTS.—When we mentioned some weeks ago the "art" mounting papers of Messrs. Houghtons we commented on their

suitability for the modern plan of multiple mounting. Messrs. Houghtons have now still further eased the way of the "multiple-

mounter" by issuing the boards in several stock sizes, in each composed of one board dry-mounted on another suited to it. The so-called "Ruskin" mounts are issued in two series, I and II. The former in browns and creams suitable for sepia, platinotype, and carbon-toned bromide and other warm-toned prints, and the latter in greys, blacks, whites, and greens for black and white prints. The prices per packet of one dozen in the following sizes are:—Quarter plate, 1s.;  $5 \times 4$ , 1s. 3d.; postcard, 1s. 3d.; half-plate, 1s. 9d. mounts present beautiful combinations of texture and colour, and the only suggestion we can make is that the inner board should be mounted, not in the centre as those we have seen, but slightly raised above this position.

#### CATALOGUES AND TRADE NOTICES.

A NEW EDITION of the "Lilywhite" Photographic Cyclopaedia has been issued by the Halifax Photographic Co., Halifax, by whom it is sent post free on application. This C edition gives a number of useful formulae for the use of the various "Lilywhite" products.

OZOBROME ENLARGEMENTS.—A circular of prices of ozobrome prints and enlargements from negatives and bromide prints has just been issued by the Ozobrome Company, 112, Allcroft Road, Kentish Town, London, N.W. The peculiar facility of the ozobrome process permits of very moderate prices, and there is the additional advantage that when necessary, a bromide enlargement can be taken off by the photographer and despatched for ozobrome copies, whilst the negative is retained for other purposes.

## ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, February 4, the President, Mr. J. C. S. Mummery, in the chair.

A demonstration of the oil-printing process was given by Mr. John H. Gear, who, after dilating on the control permissible with the process, proceeded to give the working details which he had found satisfactory. A good size of print, Mr. Gear thought, was whole-plate, which was large enough for exhibition and not so large that the process of pigmenting became excessively tedious. Nevertheless, he often expended two or three hours on pigmenting a print this size. The gelatine of the paper should be thinly coated. He was not his experience that a thickly coated paper was necessary obtaining richness in the prints. The most suitable paper which had come into his hands was the No. 76 double transfer white of the Autotype Co. The No. 77 was a similar paper, but cream. The sensitiser consisted of

Ammonium bichromate .....	100 gr.
Sodium carbonate .....	10 gr.
Water .....	4 oz.

The part of this solution was mixed with two parts of alcohol to make the sensitiser, mixed at time of use. The mixture was applied to the surface of the gelatinized paper with a 2½ in. hog-hair brush, taking care to allow none to reach the back. Streaks, which were visible while the paper was wet, disappeared as it dried, and it is necessary to dry the paper absolutely, and at the same time to protect it from the slightest ray of daylight. Any faint action of light, which would be of no account in carbon printing, formed a film of insoluble gelatine on the paper and led to flatness and addensities in the pigmented prints.

When the paper was dry it was full of curl, and therefore before printing he found it well to press it for five or ten minutes in the printing-frame between the negative and the back without applying the springs to the latter. As regards exposure, it might be anything from two to twenty minutes or longer, according to the negative and the light, but a negative of good contrast but with no blue, such as the lecturer handed round, would print in bright winter light in four or five minutes. It was most important not to examine the print in daylight, but to bring it into a room lighted only by artificial light, such as gas or incandescent electric. When printed, the image was visible, and the printing should be done until the details were just faintly visible in the high-lights. In developing, the print was simply evenly wetted in water and then washed for about half an hour. The even action of the water was important, because if air-bubbles were left on the print at the first wetting it would be found that the marks would show when pigmenting. Mr. Gear advised beginners to dry the paper after development and re-soak it in water for half an hour before pigmenting. It could be kept for any reasonable time between these two operations, but even if wanted quickly he considered it an advantage, as the gelatine film then became more resistant.

In placing the wet print for pigmenting, he laid it on a piece of ordinary paper and carefully wiped off excess of water with fine filter muslin which had been previously well boiled (to remove particles of fluff from it) and dried. The print, after removal of the water in this way, was laid upon several thicknesses of blotting paper or "Robosal" board which had been soaked in water.

As regards the inks, the lecturer pointed out that they were the most troublesome part of the process. The stiffer the ink the more unsuitable was the print, but at the same time the more fully would the sensitized tissue have to be exposed: a thinner or softer ink would suit a less exposed print, and would give softer results. Not only that, but an ink which was suitable for one working temperature was not so for another, and again, when a print occupied the time in pigmenting, the ink which was in the right condition at the start would dry to a stiffer consistency in an hour or so, with the result that the worker would be in the position of applying ink with a harder consistency than that first applied to the print, a circumstance which was certain to result in failure. His own preference was to work with a slow-drying ink. For softening the ink, megilp had been recommended, but the lecturer succeeded better with linseed oil. A great cause of trouble was dust whilst the prints were being: it might be sprayed off with water, or sometimes brushed off when the print was dry with a hog-hair brush. As regards

brushes, Mr. Gear said he could work only with the so-called *pie-de-biche* (hind's foot) pattern. The worker should learn to hold them in his hand during pigmenting, not to lay them down where they could pick up dust or have their shape injured. They should be cleaned after use in petrol and put away with their protecting caps.

In the after-discussion Mr. Gear was asked where the brushes he used could be obtained. He replied that the few he had had been purchased by himself in Paris. (*Pied-de-biche* brushes as used by M. Puyo are sold by M. Bullier, 5, Rue Charlot, Paris.—Eps. "B.J.") Another speaker mentioned that he had purchased suitable brushes from a firm named Smith, of 117, Hampstead Road, N.W.

The inks Mr. Gear employed were litho' inks, but he believed M. Demachy used fine copperplate engravers' ink. Asked whether a rough paper might be used in the process, the lecturer said the roughest he had used was the Autotype Company's double transfer "cartoon." It was found that owing to the swelling of the gelatine coating a paper which was fairly rough was just as easily worked while it was wet, owing to the protecting gelatine, and when it dried the shrinkage of the coating produced the roughness desired in the finished print. Commenting on the use of a roller for pigmenting the lecturer said he had made some experiments, but was not yet in a position to recommend the practice. A speaker advised the use of a nap roller such as used by practical lithographers.

HULL PHOTOGRAPHIC SOCIETY.—The Secretary gave a demonstration on how to obtain rich brown tones on gaslight and bromide papers by the "sulphide" method, but without the somewhat objectionable smell given off with sulphide. The tones on gaslight papers are more reliable, it being a well-known fact that the quality of the tone on this brand of paper with sulphide has hitherto been unreliable.

The demonstration was a great success, and has set quite a number working the process on account of the beautiful rich browns obtained. The only smell is that of ammonia.

The prints are well washed, as usual, to clear them of hypo, and then bleached in any bleachers as used in sulphide toning. Then they are washed and toned in a bath composed of

1 grain of ammonium thiomolybdate.
10 minims .880 ammonia.
2 oz. of water.

The prints are then rinsed and cleared in a 5 per cent. solution of .880 ammonia (1 drachm to 20 oz. of water), which clears up the high lights or whites of the picture. The toning bath can be increased according to the size of the prints, and it is slow in action, which gives one time to watch the progress. Whilst thiomolybdate is rather expensive, it will be seen that it goes a long way, and the richness of the tones is sure to please many amateurs.

CENTRAL TECHNICAL COLLEGE PHOTOGRAPHIC SOCIETY.—Owing to Mr. Clougher's lecture on "Cinematography" having been postponed to February 12, the Society held its first lantern evening on Wednesday, January 29. Slides were shown by the Chairman, Messrs. Budden, Clougher, Roche Lynch, Runeckles, Tidmas, Vincent, Whitty, and the Hon. Sec., and a very enjoyable evening was spent.

SOUTH MANCHESTER PHOTOGRAPHIC SOCIETY. — On Monday, January 27, Mr. W. F. Slater, of Kodak, Ltd., lectured on "The Theory and Practice of Time Development." He dealt with the old method of ocular development and its disadvantages, and followed on with a description of factorial development, slip development, and time development.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—"Carbograph" was demonstrated on Monday, February 3 last, before the members of this Society, by Mr. Jackson, of the Rotary Photographic Co.

CROYDON CAMERA CLUB.—The mechanical manipulation of the finished negative and the gentle art of "faking" were respectively dealt with by the President (Mr. J. M. Sellors) and Mr. Harpur. The first-named illustrated retouching, and the various methods of local reduction by abrasives, "Negafake" pencils in this connection being highly recommended for reducing small scattered lights. The correct way to "knife" the film was also shown, a somewhat deli-

cate operation for the average amateur to undertake, but accomplished in quite professional manner by the demonstrator, with the aid of various surgeon's scalpels possessed of a razor edge. The anxiety displayed by the President for the safety of these instruments on the approach of some members to examine them compared favourably both in manner and temper with a gouty patient's solicitude for an inflamed big toe.

Mr. H. P. C. Harpur, who as a matter of fact preceded Mr. Sellors, arrived late, but at once got into his "stride" and maintained it with unabated energy for a considerable time. On the subject chosen there is little doubt that Mr. Harpur could speak continuously for a week at least; it was therefore excusable that the eventual slackening was due to a hurried whispered communication from the Hon. Secretary.

Amongst the various systems of faking shown and explained, a most ingenious method of combining figures, or sheep, or cattle, with a landscape was brought forward, and may be new to some. The case taken was that of introducing sheep. The negative containing them was first very carefully blocked out, leaving only the sheep visible. A transparency by contact was then made, and placed film to film with an unexposed plate, both being attached to the enlarging easel, transparency outwards. The landscape negative was next placed in the lantern, and projected on to the sensitive film through the transparency, and the former developed and fixed in the usual way. The resulting composite transparency can obviously be adjusted in absolutely correct register, and is employed for making a fresh negative, enlarged or otherwise. The method has certain apparent limitations. In the example given, for instance, it is presumed that the transparency of the sheep has sufficient stopping power to prevent their recording on the adjacent film. If this occurred to a slight extent, Mr. Harpur said (presumably referring to the ferricyanide reducer) "that a touch of Howard Farmer would rectify matters," or alternatively transparent parts in the sheep transparency might be temporarily blocked out. Some general reduction either of the sheep or of the landscape transparency might also be necessary to produce a harmonious whole. He had further elaborated the system so as to print in a sky as well. In this case the sky would be separated from the landscape portion by the thickness of the glass. The slight unavoidable diffusion in the reproduction in the negative form was generally an advantage rather than otherwise.

During the evening Mr. S. H. Wratten exhibited a new dark-room lamp, fitted with various safe-lights, a sliding panel bringing one or the other into use; so far as possible he had made it "fool-proof," and he had much pleasure in presenting it to the club for the use of its members.

**SOUTHAMPTON CAMERA CLUB.**—On Monday evening last a lecture competition was held, when Mr. Smith Whiting was adjudged the winner. He gave a brief account of bird-life photography, which was illustrated with some excellent slides. Mr. F. G. Ryder also gave an amusing short description of camp life and Mr. W. R. Kay concluded with a brief account of his mountaineering experiences, which was accompanied with a series of splendid views of the notable peaks in Switzerland.

## Commercial & Legal Intelligence.

**BRITISH PHOTO. PAPER COMPANY, LTD., LAMBETH, S.W.**—Lien January 20, £50 6 per cent. debentures, part of £5,000; amount previously issued, £3,290; no (assets).

**DISSOLUTION OF PARTNERSHIP.**—The partnership existing between Frank Victor, Horace Sinkins, and William Henry Franklin, photographers and photographic dealers of Slough, carrying on business as The Artistic Portrait Company, has been dissolved by mutual consent. All debts due or payable will be received and paid by Frank Victor Horace Sinkins.

**NORWICH BANKRUPTCY.**—A receiving order in bankruptcy has been made against Percy John Swain (carrying on business as John Percy), photographer, of 37, Earlham Road, Norwich, formerly in partnership with Louis Smith as Louis Smith and Co.

## News and Notes.

**KODAK, LTD.**—Information has reached us that, owing to the retirement of Mr. George Davison from business, there will shortly be a change in the managing directorship of Kodak, Limited. Mr. Davison's successor to the post is said to be Mr. W. S. Gifford who is already well known to the various departments and members of the firm for his ability, tact, and courtesy.

**"THE PHOTO-MINIATURE."**—We are asked to announce that, commencing with the present month, arrangements have been perfected whereby "The Photo-Miniature" (established 1899) will in future be published at regular monthly intervals throughout the year. The current issue is devoted to the subject of "Tank and Time Development." "The Photo-Miniature," which is freely illustrated, treats in detail of a different subject each month, and in its new pages gives a comprehensive survey of photographic progress in all parts of the world. Most of the eighty-four published numbers of "The Photo-Miniature" are in print and, together with copies of the current issue, are obtainable of the London agents Messrs. Dawbarn and Ward, Ltd., 6, Farringdon Avenue, London E.C., and of all photographic dealers. Price 6d. per copy.

**THE TEMPLE OF FAME TO-DAY** (writes the *Telegraph's* Paris correspondent) is the photographer's shop. Whose portrait is the best known? The result of an inquiry made is only what we expected for a fair lady comes out at the top of the list. Take a hundred photographs of living celebrities sold in the Rue de Rivoli, and fifteen of them will be found to represent Madame Otero, called "the beautiful." This is only as it should be. But it is a little surprising to learn that the second place is equally divided by Raoul Boucher, a muscular music-hall wrestler, and by M. Pierre Loui who is surely the antipodes of a prize-fighter. Parisian eclecticism is thus proved. The divine Sarah comes only third with eleven pictures per cent. Mademoiselle Cléo de Mérode, a once famous dancer about whom a young writer some years ago wrote a thin philosophical treatise "On Cléo de Mérode, considered as a Popula Symbol," shares fourth place with a novelist whom one had not hitherto thought so very famous, Mr. Félicien Champsaur.

**THE ROYAL SOCIETY OF MINIATURE PAINTERS.**—The thirteenth annual exhibition of the Royal Society of Miniature Painters, is now on view at the Modern Gallery, 61, New Bond Street, W. The exhibition will be open to the public until February 22.

**A "ROTARY" COMPETITION.**—The current issue of "Photo Notes" announces a competition in which six prizes of half-a-guinea each are offered for prints suitable for reproduction as frontispieces to our worthy contemporary. A similar competition open to professional photographers only is announced. Further particulars will be found in the February issue of "Photo Notes" just published.

**THE NEW AMPHITYPE PROCESS,** also the Vandyke direct zinc process, will be demonstrated for the first time in the United Kingdom by Mr. Archer Clarke, at the new premises of the London and Provincial Photographic Association, "The Old Napier," 25, High Holborn, W.C., nearly opposite Chancery Lane, on Thursday, February 20, at 8.15 p.m. Admission free.

**"THE RAJAR" CAMERA,** offered monthly by Messrs. Rajar, Ltd., of Moberley, Cheshire, for the best print on "Rajar" P.O.P., has been awarded to Dr. F. G. Baker, Ellenborough Park, Weston-super-Mare, this print having been judged the best received during January. The paper on which the print was made was purchased from Messrs. The Postal Photographic Company, Rotherham.

**CINEMATOGRAH EXHIBITIONS.**—At the meeting of the London County Council, on Tuesday, the following motion, proposed by Mr. Reynolds, and seconded by Sir John Benn, was agreed to unanimously and without discussion: "That, in view of the highly dangerous character of unlicensed cinematograph exhibitions, the Home Secretary be asked to receive a deputation from the Council to urge the necessity for immediate legislation to make it illegal for cinematograph exhibitions to be given in premises which have not been licensed for the purpose, and that the Theatres and Music Hall Committee do make the necessary arrangements for the deputation."

## Correspondence.

*Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

### PHOTOGRAPHERS AS PROFESSIONAL MEN.

To the Editors.

Gentlemen,—*Re* etiquette among semi-professional photographers, have heard of a photographer who was taking views for his company, going into a certain district, and buying a packet of postcards, or a book of views, and copying the views from the same standpoint, and calling them standard views. Can he call them his own? I think not; they are, as you say, piracy in its worst form. I think every photographer should be capable of choosing his own views, or position, and being a little original, and not living on other people's brains.—I remain, yours faithfully,  
Swindon.

NUNQUAM.

To the Editors.

Gentlemen,—I think "Status" is taking the case of photographers being recognised as professional men in too serious a light. I fully endorse his remarks regarding our leading men and others having ouch and ideals shown in their work, and I am sure that not one of such men turning out artistic efforts of the highest merit, have any cause of complaint against their social position. As far as raising the standard of photographers is concerned, I should like to ask, who can do this better than the worker himself? The work of an artist will always meet with merit, and as far as the rest are concerned, I am afraid they must remain photographers, and reap their money-grubbing reward, which to the true artist is of secondary consideration.

Another point is this. He suggests the weeding out of the unfit. Who are the unfit? The midget man may turn out technically sound photography, though he certainly is not raising the standard of the photographer.

No, it won't do. Each worker must rest content with his own reward, which he will find of greater satisfaction than any brass plate.—Yours truly,  
L. R. GOODYER.

The Goodyer Studio,  
33, High Street, Bognor.

### AGAR-AGAR EMULSIONS FOR PAPERS AND PLATES.

To the Editors.

Gentlemen,—We notice, in the issue of "The British Journal of Photography" for January 31, 1908, page 79, that you publish an article on the paper read by us before the Royal Photographic Society in December last. Perhaps a few notes referring to your remarks may be of interest.

The method suggested by you for filtering the agar-agar should do admirably; we tried to obtain a small centrifugal machine for experiments, but were unable to do so. We will, however, fit up a centrifugal apparatus and allow the hot agar solution to set in it. We will communicate the results to you, giving details of speed, etc.

You say that, at the present time, the value of agar will be as a vehicle for papers; in this we entirely agree with you, and we would mention that we have coated several batches of 2 to 4 litres on a machine (of the Flinch (?) type) actually used for the manufacture of large quantities of paper in a factory. In this work, straining through linen was found to be quite sufficient. At first we used bainsook, but this left suspended matter in the agar, so that, on drying, the paper showed glistening specks on the surface. We feel convinced that the question of filtering is not a difficult one for the purpose of manufacturing papers; the only English agar paper on the market shows no marks caused by insufficient filtering. We suggested the use of filter paper for those purposes where a perfectly

clear solution is needed, such as work on plates and films, or for chemical work. In these experiments on a large machine, we coated several lengths of paper, some measuring about 100ft. and some less; it was festooned, dried, reeled, and cut up, in an actual factory, precisely as is done with gelatine papers. The papers showed no cracks whatever, but on the contrary seemed to be coated most perfectly.

With regard to rapid drying, though most of our batches are dried in half an hour to an hour, nevertheless we have had some coatings wet for fifteen to twenty hours, without any signs of cracking. The only trouble we have had has been due to the curling of the edges of the paper; but, as will be seen later on, we use special paper, and this is of importance. The wet solution which has been allowed to set on glass, does crack when pushed with the finger, as you say; it is what may be termed "short" and tender. But we have never noticed any tendency whatever to crack on paper, in any stage; nor will the film crack on glass when once it has been dried. We have been attempting to make long films of agar, and have found that it was very difficult to manipulate the wet film; when once dried, its tensile strength is considerable.

You mention the peculiarity of agar, that when deposited on a glass plate, it causes a film of water to separate out between the plate and the pellicle; we found this also, but when once the pellicle has dried on the glass, or even partly dried, it adheres to it very firmly, and can then be washed with hot water and treated somewhat roughly. Indeed, sometimes the pellicle cannot be removed from the glass, except by boiling with aqua regia.

With regard to your remarks on maturing, we are making a series of experiments, the results of which we shall communicate later. The bromide paper which we showed had a speed equal to that of Nikko, and it was obtained by heating our emulsion to 100 deg. C. for five minutes; we believe that this is a greater speed than would have been obtained if gelatine had been used.

To refer again to coating on paper. The quality of the paper itself is a subject to which a considerable amount of attention has been given, as upon it depends much of the success of using agar. Paper upon which an emulsion, whether in gelatine or agar, is laid, consists of a basis carrying a layer which should be impermeable. The basis, even in some of the best papers, consists largely of wood pulp, and often starch. The impermeable layer contains pigments which are composed of various substances; the object of this layer, we take it, is partly to obtain a surface free from marks or specks, and partly to prevent the chemicals from "wandering" into the basis. If they do so wander, the paper and the chemicals interact and the P.O.P., as such, is spoilt. The impermeability of the second layer is obtained by us by coating a plain paper with a solution of agar, and drying. Wood pulp consists of a class of cellulose—lignocellulose—which is very much more reactive than pure cellulose, and which is much more liable to deterioration, therefore, than pure cellulose. On this account we tried to obtain some papers for P.O.P. emulsions made of pure rag pulp; being unable to do so, however, we had some plain paper made specially for us. This is liable to contain specks of iron, but the presence of these marks can be obviated by replacing the iron beaters used in the manufacture of the pulp by others made of different material; so that this should not cause trouble. We tried using this plain paper without any second layer, but it was too porous.

Our paper is made of nearly pure rag pulp, specially sized, coated with a solution of agar, dried, and reeled; this is then coated with the emulsion and dried in the usual manner. One of us has taken out a patent covering this, and for that reason no mention of any work on papers was made when reading our paper before the Royal Photographic Society. This may appear to have been an omission, but we thought it undesirable to discuss work in which we had a commercial interest.

This paper was adopted as a result of our attempts to get a paper least likely to "go wrong." We find that it is superior to any other, dries quicker, keeps well, and holds the emulsion better than any other we have tried. Of the samples of paper as ordinarily used which we have tried, some gave good results and others bad, using the same emulsion; some were hard and others soaked up the emulsion or water as though the surface was all chalk; moreover we heard that it was impossible to obtain a supply of the best paper. Since adopting this special paper, it has been found out that agar emulsions on papers ordinarily used for emulsions, are liable to give bubbles when toned, etc. We have not examined this yet, but we

note that very few of our experimental coatings show it. The expansion of agar on soaking is not great; a piece of film, dried at 100 deg. C., then soaked in water for two days, expanded 1.8 per cent. in linear dimensions; this is less than gelatine.—We are, Gentlemen, yours faithfully,

W. F. COOPER, B.A., F.C.S.

W. H. NUTTALL, F.C.S., F.I.C.

#### GLAZING P.O.P. PRINTS.

To the Editors.

Gentlemen,—Noticing recently that several of your readers have complained of gelatine prints sticking to the glass when being glazed I may add a little of my experience. Until I treated my prints or postcards (P.O.P., bromide, and gaslight) in the following manner I frequently had trouble in glazing, but now I never find one to stick. After washing the prints thoroughly from free silver (in the case of P.O.P.), I place them in an alum bath of 8oz. to 80oz. of water. In this they remain ten minutes, and I then wash and tone them in the usual way, drying them completely before passing to the glazing process. The plate glasses for this latter are prepared as follows. A small piece of cotton wool is well soaked with methylated spirit and the glass cleaned with this, rubbing over with a clean cloth. In wetting the cotton wool with spirit I simply hold the wool to the neck of the spirit bottle, give the latter a shake, and clean the plate with the quantity of spirit thus absorbed. I then French chalk the glass and rub clean with another cloth. Water from the tap is now allowed to run all over the glass two or three times, and without wiping but straight from the tap the glass is placed handy for the prints to be placed on it. These are then squeezed firmly down and left to dry. The secret lies in letting the tap run on the glass after polishing with French chalk. I have polished some thousands and never had a single one stick after using the above method. I am sure of those of your readers who have had misfortunes in this direction will try this method, they will find that it guarantees success.—Yours truly,

56, Castle Road,  
St. Albans.

JOHN DE VOIL.

#### MR. FREDK. H. EVANS'S PHOTOGRAPHS AT RUSSELL SQUARE.

To the Editors.

Gentlemen,—Your kindly critic on my R.P.S. exhibition says there are no new things there. May I point out that there are sixteen prints now exhibited for the first time, and that nearly all the sixty on the walls have been specially mounted for this exhibition to show as great a variety as possible in this method of mounting.—Yours, etc.,

FREDERICK H. EVANS.

34, Fox Hill, Upper Norwood, S.E.

#### THE "B.J." IN ASIA MINOR—AND ELSEWHERE.

To the Editors.

Gentlemen,—We notice one of your advertisers mentions this week that they have received a reply to an advertisement from Turkey-in-Asia, and, peculiar to relate, we received one reply from Kania and one from Amassia, both in Asia Minor, and also inquiries from Columbia and British Guiana and Peking, all this week. This seems to show that the "British Journal," as far as we can see, practically holds the sway the world over, as we receive hundreds of foreign communications every year as the result of our advertising. The above refers to the "British Journal of Photography."—Yours truly,

THE HALIFAX PHOTOGRAPHIC COMPANY.

Halifax, February 3, 1907.

**DEATH OF A VETERAN PHOTOGRAPHER.**—Mr. Henry Gordon, who for many years carried on business as a photographer in Aberdeen, died on January 31 at the residence of his daughter. Mr. Gordon was in early life a gamekeeper, but while employed in Perthshire he took up the study of photography, and prosecuted it with considerable success. In 1858 he commenced business as a photographer in Aberdeen, first in Union Terrace, and subsequently at establishments in other parts of the city. Mr. Gordon was eighty-six years of age.

## Answers to Correspondents.

#### PHOTOGRAPHS REGISTERED:—

A. C. Milne, The Studio, Brechin. *Two Photographs of the Rt. Hon. James Alexander Campbell, M.P.*

W. Skewes, 1, Park Crescent, Wigan. *Photograph of the Wigan Football Club.*

G. de B. Porter-Higgins, Leighton Studios, Redcliffe Road, South Kensington. *Photograph of Geo. Belcher.*

A. Russell, 6, Wild Street, Liverpool. *Photograph of Fred. Lindsay, Champion Whip Manipulator.*

**DYE MORDANTS.**—I wish to coat glass thinly with gelatine, dye it, and then, without varnishing, render the dye waterproof. Can you inform me (1) what dye or mixture of dyes will give me a good orange red shade, (2) what dye or mixture of dyes will give me a good blue, and (3) what mordant to use in each case?—JUVENIS.

(1) Filtered (Hoechst), or tartrazine and rose Bengal, bolam red, Biébrich scarlet, fast red, azo red, etc. (2) Methylene blue, victoria blue, naphthylamine blue, patent blue, etc. (3) It is impossible to answer this question satisfactorily without knowing exactly the dye that is to be used. We cannot say which dye will answer our querist's requirements, because we do not know what he is aiming at. We would suggest that a careful study of the handbooks on dyes and dyeing, to be found in the Patent Office Library, which is open free from 10 to 10 daily, would enable our correspondent to find the correct mordant to use when he has found the dye that will suit his work. We have only mentioned a few dyes, but there are hundreds of red and blue dyes which will dye gelatine, and we cannot spare the space to enumerate them all with the necessary mordants. Naturally, it occurs to us that it would be possible to render the dyed gelatine insoluble and impermeable by the aid of any of the well-known hardening agents.

M. S.—The instrument is a very well made meter of the "extinction" type. It is a question whether this is preferable to others of the sensitive paper pattern.

J. W. D'A.—A most reliable method is that on p. 808 of the "Almanac."

**TESTS FOR HYPO.**—1. Will you be good enough to give me one or two simple tests of detecting the presence of hypo in water solution and raw paper? 2. Also the test for iron? 3. Could you tell me where I could obtain a book containing simple chemical tests not too complicated for one not having much chemical knowledge.—SAM JONES.

We prefer the iodide test. Boil a fragment of starch in water to a clear solution, and when cool add a drop of tincture of iodine. The solution is dark blue. A test tube of water, tinted blue with a drop of this iodine-starch solution, will be decolourised by solution containing hypo. Another test is the "permanganate": Dissolve 2 grs. potass permanganate and 20 grs. potass carbonate in 40 ozs. of water, and similarly tinge a test tube of water pink with this stock solution. The colour is discharged on adding solution containing hypo. In the case of raw papers, soak in water, and test as above. 2. Solution of potass sulphocyanide gives a red coloration. 3. We should say one of the books on raw papers would be of service to you, but tests applied without some experience in chemical testing are not likely to be of much use.

**ENAMEL TABLETS.**—Could you inform me where I could obtain the enamel tablets for use in connection with your article, "Profitable Forms of Carbon Printing," in issue dated January 24?—SEEKER.

The enamel tablets may be had from Messrs. Lecherlin Barbe, Ltd., 95, Jermyn Street, London, S.W.

E. W.—Contrary to our custom to make distinctions in such general terms as you suggest. If you can name the specific class of work for which you propose, we might be able to assist you.

**FORMULÆ.**—(1) Will you kindly give me a recipe for making ink for a metal stamp which, when dry, will be glazed or enamelled in appearance, similar to the impression from a printer's copper plate, which is used for notepaper? The ink for the above metal monogram was made according to your recipe for ink for rubber stamps, page 840, "B.J. Almanac," only I used aniline green dye. (2) Also re ground glass varnish (page 807, "B.J. Almanac"), does the increase of benzole give a finer and thinner matt surface, and may aniline dyes be used for tinting? (3) Also, would you tell me whether malachite green, aurantia, etc., are dyes, and if about the same price as aniline dyes?—C. W.

(1) You must not expect to get the same effect from an ordinary stamp as is obtained on the embossed headings of notepaper. For

hose a special ink, of a fatty nature, is employed. It may be had from any of the houses that supply printer's materials. Possibly, if you were to add some gum to the ink you are using you would get a higher gloss. (2) The increase of benzole adds to the coarseness of the grain. (3) They are, and about the same price.

**PLEX.**—Of the cameras, K and M are practically the same instrument, and a very strong and reliable one, too. L is perhaps more used than any other camera of the kind, and is the best, in our judgment, for hard professional work. The latest pattern (with new pattern shutter) is as perfect as can well be. N is a beautiful instrument, but not quite as strong as V, and not quite as convenient, for your purposes. Of the lenses, we should advise one that can be worked at  $f/4.5$  when required, and should advise D or F. I is equally good, but its separability into two single lenses is not an actual gain upon such a camera. E, at a somewhat smaller aperture, is also in every respect a suitable lens. We advise you to select a half-plate size for press work, and a focal length of 8 to 9 inches, not more than the latter.

**ING.**—The formula as you have made it up is practically the same as that given by Namias. The article stated that the bath in question had not the same rapidity of action as others with more chrome alum in them. We suggest that the slowness of your negatives in drying has not been due to the bath, but to the recent cold and damp weather.

**ERTURE.**—The great aperture is obtained by air spaces in the lenses, a construction which calls for more careful shielding of the lenses from direct strong light than is the case with cemented double lenses such as the second one you name. This constitutes the most important point to be considered. As a rule, the large-aperture lens will be equal, if not superior, to the  $f/6$  lens when stopped down to this latter aperture.

**W.**—1. It does not follow that the omission of mention is a proof of non-popularity. It is usually a question of discount and profit to the wholesaler or retailer. You would not be correct in supposing that the instruments are less suitable for their purpose. They are certainly of a very high order. 2. Of the two we should select E.

**E.**—It is a very good lamp, and has been much used by the best flashlight workers, but you will not find much difference as regards smoke compared with other good powders, though less than with the powder blown through a flame.

**P. A.**—The address of the secretary of the Professional Photographers' Association is 89, Albany Street, London, N.W.

**DIUM SULPHIDE.**—1. Can you please tell me how much of the saturated solution of sodium sulphide I should take to equal 1 oz. of the dry crystals? I find it impossible to keep this salt dry. 2. Re the instructions recently given for making lantern slides by the albumen process, can the albumen be bought ready prepared? If so, where? 3. Should the eggs used for the purpose be new-laid, fresh, shop, or cooking eggs?—CHARLES MARSHALL.

1. The best way is to make a solution of definite strength—say, one part of sulphide to two of water; then you know what you have got. That is better than relying upon "saturated" solutions. 2 and 3. Good fresh eggs are all that is necessary. It is not well to employ preserved eggs for the process.

**STUDIO.**—I have to build a new studio, as per sketch. I should be pleased to receive your advice as to height, shape, amount, and if my particular glass. I have a free hand, and can build as I like, but it must be in that position, and available for electric light.—NEW STUDIO.

We must refer you to pages 635 and 659 of our last volume, August 23 and 30 last year. In these articles you will find all the information you desire. It is very fully given—much more so than can be done in this column. The proportions 30 x 40 ft. will enable you to do all that is required in professional portraiture.

**ATE MARKING.**—1. Can you kindly tell me how the plate-mark impression on the enclosed card is done, and when—before glazing or after? 2. If I need a press, where could I buy one?—W. S.

1. The plate marking is done, after the glazing, as follows:—Have a plate of zinc or copper the size of the desired mark, lay that on the bed of a rolling press, place the print in position on it, and roll it through with a piece of thick india-rubber, or printers' blanketing, on the back. 2. At any of the dealers.

**ING RESIDUES.**—1. We have a quantity of silver waste, i.e.,

washing from silver prints before toning. Do you recommend rough salt or acid for throwing down before drawing the clear water off? Also, do you test same first with a weak solution of liver of sulphur, to see whether all the silver has been thrown down? 2. Also the silver waste from hypo fixing baths; do you throw this down with liver of sulphur, and test with the same?—W. B.

1. The common salt is usually employed. If the precipitate does not subside in a day or two, add a little hydrochloric acid and well stir. If the addition of a solution of salt to the clear liquid does not produce cloudiness you may know that all the silver has been precipitated. 2. Yes, in both cases.

**WAGES QUESTION.**—Kindly give me your answer to the following: Mr. —, of —, advertised for an operator and retoucher. I answered the advertisement, and sent specimens of my own operating and retouching, asking £2 2s. per week. I also gave references for two and a half years, and was engaged for the 20th of January. Of course, I left Manchester on the 18th. I was put to retouch at a window that is painted inside all over, and I asked him if he had not got a better place to retouch. Of course, he said that was all right. Well, I asked for a mirror, to make the best of it. But it was not a success. On the 21st, in the evening, he told me to quit work, and clear out. Now in that case I consider I am entitled to two weeks' wages. On Friday (24th) he sent me one week's wage, and considers this final. I am sure in all my experience I never had anything like it. I will abide by your opinion.—RETOUCHER.

It appears that probably the work did not suit, possibly it was not up to the specimens shown. It may be that the second week's wages might be recovered in the county court, but if the work done by the querist in his new berth was not equal to the specimens he submitted that is doubtful.

**STUDIO LIGHTING.**—My present studio light gives exactly the lighting I require for the majority of sitters without blinds. For brighter days in the near future I shall require to get the same effect while softening light for sitters' eyes. How can I do this without degrading the high lights? A reply in your esteemed journal will oblige.—SIMILARITY.

As no mention is made of the form of the studio or its aspect, we can give no advice. All we can say is that you use screens or blinds to stop out such light as is not required.

**PRINTS ON CHINA.**—I have an order to do some photographs on china plates. They must be transparent (but not carbons). I was told they were printed and toned in the ordinary way, either on collodion chloride or gelatine chloride—I do not know which. If you can assist me I will be very much indebted, as I do not know how to proceed. The only information I could get was that they were put down on glass, and when dry the paper was stripped off, leaving the film, which was then transferred to the plate. This is where I find the difficulty.—W. C.

As you describe the method we must confess we do not understand it. However, it must be a troublesome and roundabout way of doing the work. By far the simplest way is by the carbon process and the results not only the best, but are more permanent than those by any silver process.

**BLEACH-OUT PAPER.**—(2) I have been trying to find out how the Uto paper is made. Can you tell me what dyes are used? In the note on Uto paper in the "Almanac" it mentions turpentine, apparently as a sensitiser. Does it mean mixed with bichromate or chlorides? I suppose the dyes are coal tar, as they bleach out with benzole.—LILIAN E. BLAND.

(1) C/o The American Express Company, Waterloo Place, London, W. (2) Details of the manufacture were published in Dr. Smith's patent specification, published in the "B.J." for October 11, 1907. Turpentine as a sensitiser is quite independent of bichromate, as you will see on referring to the specification above quoted.

**THREE-COLOUR FILTERS.**—1. Under what name are the new rapid filter dyes of Messrs. Meister Lucius and Brünig sold? 2. Please give formulæ for filters, using the new rapid filter dyes—blue I., green I., and red I. 3. Do the formulæ issued with the old dyes apply to the new ones also? 4. Should not Prof. Novak's formulæ on p. 840, "B.J. Almanac, 1907," read: Water 150 ccs., instead of 1.50 ccs.? 5. Assuming 150 ccs. to be correct, the formula would figure about 1.31 grain of green dye and about 1.15 grain of red dye to the square inch of finished (cemented) screen, while the directions accompanying the dyes figure out 1.57 grain for the

green—about one-half the strength, and 1-72 grain per square inch finished filter for the red screen, about 1-5 the concentration of Prof. Novak's formulae. If both sets of formulae are correct, I do not quite understand how Novak's filters can transmit 33 per cent. more light. Will you kindly explain this if possible? 6. I send you small sections of flexible filters made substantially in accordance with the formulae sent out with the above dyes, a copy of which I enclose. Will you kindly give your opinion of them?—**PHOTO-COLOUR.**

1, 2, 3, 5, and 6. There is no reason to suppose that the dyes you have obtained are not correct. The filter strips seem to be the colours given by the new filter dyes of Meister's. We do not think they are the best for three-colour work, and we enclose you formulae for three-colour filters, which have given the best results in three-colour work. If you were to try these dyes—which you can easily obtain from the agents of Meister Lucius and Brüning—you would find them much more satisfactory. We should certainly advise you to test the filters on a spectrum camera if possible, or at least on a pocket spectroscope. You could buy Wratten's gelatine strip ready prepared and spectroscopically tested for 2d. per square inch.

#### FORMULÆ.

To coat 100 sq. cm., take 16 ccs. 10 per cent. gelatine, which should contain the following quantities of dyes for 100 sq. cm. glass:—

Red filter	Rose Bengal .....	.08	gm.
	Rapid filter K (yellow) ...	.08	gm.
	Gelatine .....	1.6	gm.
	Water .....	16.	ccs.
Green filter	R.F. green .....	.01	gm.
	Naphthol-green .....	.01	gm.
	Rapid filter K (yellow) ...	.01	gm.
	Gelatine .....	1.6	gm.
Blue filter	Water .....	16.	ccs.
	Victoria blue B .....	0.03	gm.
	Naphthol-green .....	.006	gm.
	Gelatine .....	1.6	gm.
	Water .....	16.	ccs.

4. The formula should read 150 ccs.

**FLASHLIGHT.**—I have read the JOURNAL for the past thirty years. This is the first time I have asked a favour of you, so trust you will be good enough to oblige me with any information you have on flashlight photography. I have used a "Slingsby's," and now have one lamp (large size) of "Todd-Forret." Can you say how many of the latter I require to photograph a group 40 feet wide, say 40 feet away from camera? Any advice will be welcome.—**H. F. J.**

We are afraid it is difficult to give precise information since so much depends on the colour of the surroundings, that is to say on the amount of reflected light. A very rough estimate is 300 grains of magnesium, using a lens at  $f/11$  and a plate of fair rapidity, about 200 H. and D. You can estimate from this and from the average charge of your lamp the number of lamps necessary. A more practical method would be to use a long-trail of a good flash powder, such as Agfa, making one or two experiments beforehand. The powder should be laid in a shallow trough made from a piece of tin plate.

**CIGARETTE PHOTOGRAPHS.**—Last September a firm applied to me for a group photograph of West Ham United football team (1907-8), same as you registered for me. They stated they required it for box stiffeners. I supplied them with a copy of same. Now I find a cigarette firm have issued with their cigarettes separate photographs of some of the prominent players copied from my group, which they say the above firm has done for them. These photographs form no part of a box whatever, but are individual photographs quite separate from the box, a sample of which I am sending you. What do you advise in this matter?—**A. J. REEVES.**

It is apparently a case of infringement. We take it that you did not sell the sole copyright in the photograph to the first firm, but only granted them the limited use of it for the purpose specified. In these circumstances the firm has no right to make other use of the photograph or of parts of it, and their action, as also that of the cigarette makers, is an infringement. We should advise you to write to the cigarette firm pointing out your proprietorship in the photograph, and asking them what they propose doing in the matter. It is possible they are innocent

infringers, and though that is no legal extenuation, it is often advisable to agree to, say, double the reproduction fee which would have been paid in the usual course. You should, however, make any offer in first writing them.

**DRAWING-UP LEASE.**—I intend altering premises I now occupy and taking same on lease. Would it be legal for myself and landlady to write out the lease or agreement without a solicitor, provided it was properly stamped and witnessed?—**LANDLORD.**

Yes; it would be quite legal to do so. But unless the conditions of the lease are properly specified it may lead to future litigation. There is an old aphorism: "The man who acts through his own lawyer has a fool for a client."

**J. E. GUBBINS.**—We think you will find what you want in Goetz Zeiss price lists. The lens you mention in the next size larger will cover a bigger circle than you require. Why not get this instead of the 3½ inch? A 13 inch circle is rather large for a 4¾ inch lens and not many will cover it.

**PARAMIDOPHENOL.**—(1) Please oblige us by informing us, through "B.J.," why the paramidophenol developer—

Potassium metabisulphite .....	300	gms.
Water, distilled .....	1,000	gms.
Paramidophenol .....	100	gms.

to which we add a saturated solution of caustic soda, does not develop so well and does not develop so well as the original rodinal developer. (2) In the "Almanac" is said caustic soda or potash. We suppose this to be "solution." (3) It has been said that there is some special precaution to take by mixing this developer. We would be of the kindness to inform us whether our developer is quite the same as rodinal—**VIKING (Copenhagen).**

(1 and 3) We cannot say whether this formula is the same as that used in preparing the commercial solution of rodinal. Probably it is not, if it does not keep as well. (2) This should be a saturated solution of caustic soda or potash.

**WOGHT.**—We have no objection to answering queries which call for looking up the literature of photography, but to answer you in detail would mean a week's work. Fancy a world deprived of seven days of the "British Journal"! If you will let us know the specific paper of Carey Lea (he wrote scores) we will look up for you. As for Hurter and Driffield, we must refer you to the references in Mees and Sheppard's "Investigations in the Theory of Photographic Processes" (Longmans, 6s. 6d.). The reference to Roscoe is "Phil. Trans.," 1857, p. 355-601.

**PHOTOGRAPHING FURNITURE.**—Will you be kind enough to answer the following queries in Correspondent's Column? (1) Do you know of any book published on photographing antique furniture, china, etc., or articles on this subject in any paper? (2) Can you suggest something to rub over highly-polished furniture to do away with extreme high-lights and reflections, and which can easily be removed?—**ANTIQUE.**

(1) No book is published on the subject. (2) Photographs, taken for illustrating furniture catalogues, are usually made before the furniture is polished. With antique furniture, as a rule, there is not sufficient polish on it to give trouble to the photographer, if it is lighted with diffused light, subdued. We have heard of good bodied stout being used to subdue gloss, but we have had no experience with it ourselves. It could easily be removed with wet sponge.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## The British Journal of Photography

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

### TERMS OF SUBSCRIPTION, Post Free.

(UNITED KINGDOM AND THE CHANNEL ISLES).

One Year ... 10s. 10d. Half Year ... 5s. 5d.

Quarter Year ... 2s. 9d.

## SUMMARY.

Royal Photographic Society.—The names of the new officers appear on page 127. We are pleased to say that Mr. J. C. S. Murnery has consented to accept the Presidency for another year. (P. 127.)

Mr. Thomas Bedding is announced as joint-editor of the "Photofinisture." (P. 113.)

Sepia Bromide.—A secret process again figures in the county-court. (P. 128.)

The common law rights in unpublished drawings was the subject of an interesting case in the High Court last week. (P. 122.)

The status of the photographer as a professional man is the subject of several letters from correspondents. (P. 128.)

Mr. Tilney's review of two exhibitions of paintings of London points to the enormous field still unexplored by photographers. (P. 123.)

Mr. H. E. Smith contributes some notes on his new thiomolybdate toner (p. 117), which has now appeared on the market. (P. 126.)

Mr. W. H. Smith, at the Croydon Camera Club, has some useful hints to give on platinum printing. (P. 117.)

Pinhole aperture numbers, glazing P.O.P., the development of autochromes, sepia-platinum paper, and photographic matters in the Near East are other subjects discussed in our correspondence columns. (P. 129.)

Dr. Zschokke replies to the recent paper by Dr. Wandersleb on distortion in photographic lenses. (P. 115.)

The conclusion of Mr. R. J. Wallace's paper on the modern sensitizers appears on page 119.

The advantages of a diaphragm shutter which is rapid at its highest speed is emphasised by Mr. Chapman Jones. (P. 114.)

Arc lamps and daylight changing are among patents of the week. (P. 124.)

We draw attention to the need for further experiment in the bichromate processes. (P. 114.)

A French writer recommends the convenient and efficient box form of sky-shade. (P. 114.)

## EX CATHEDRA.

**Photographers** That the French theatre has its own *And* *médecin attiré*—a doctor by appointment **Playhouses.** —is perhaps well known to theatre-goers

in France, but it is news to hear that at least one Paris playhouse has a pharmacist of its own appointment, both arrangements being entered into for the convenience of any in the auditorium who may be taken ill. The practice suggests the possibility of a photographer, in a town possessing a theatre of sufficient importance, establishing within the building either a branch studio, or, in the event of the theatre forming part of a block, his regular business premises. The opportunity of being photographed during an entr'acte would certainly appeal to ladies, and the present facilities for artificial lighting have removed any technical obstacle from such a scheme. The conditions under which business might thus be secured are certain to be rare, but they may at times prove commercially feasible.

\* \* \*

**Mr. Thos. Bedding in America.**

The large number of photographers and members of the trade who knew Mr. Thomas Bedding during his able occupancy of the editorial chair of the "British Journal of Photography" will be interested in hearing that he is now associated with Mr. John A. Tennant in the editorship of the "Photo-miniature" of New York. Mr. Bedding sailed for the States a few weeks ago, and the photographic journals of that country have already borne evidence to the activity of his pen. His knowledge of photographic matters and personages in this country is bound to be of service to our small, but energetic—and, we would say, respected—contemporary, and American readers and editors alike may be congratulated on the coming of "T. B." among them. Whether the fame of the oft-repeated "parrot story" has preceded Mr. Bedding across the Atlantic we cannot say, but our mention of it will perhaps cause it to be called for. Meanwhile, his many friends in this country will, we are sure, be of one mind in wishing Mr. Bedding all prosperity in his journalistic enterprises in New York.

\* \* \*

**A Simple Sky Shade.**

The value of a sky shade to cut off light that would otherwise be reflected on to the plate from the bottom of the camera and from the lens mount is appreciated by all photographers of experience, though it is a device that is used only by a few. By elaborating the form slightly it can be turned into a more effective shade that not only screens off light from the sky, but also protects the sides and top of the inside of the camera and lens mount from stray, useless light. In the "Photo Revue," a writer suggests a very

simple form of shade that must obviously be very effective. He takes a small cardboard box, of a kind easily obtained from a chemist or jeweller, and cuts a circular hole in one side to fit the lens and a rectangular aperture in the opposite side to admit the light. If blackened inside this should be quite as efficient as the most elaborate contrivance that a camera-maker could construct, while its cost will be next to nothing. For a lens of 3 cms. he selects a box that is 6 cms. high, 5 wide, and 4 deep, when placed in position on the lens. The aperture for the lens is cut in the centre of one of the 6 x 5 sides, and on the opposite corresponding side an aperture 3 cms. high and 2½ cms. wide admits the light to the lens. This is, of course, the arrangement suited to a vertical plate. With a horizontal plate the box is turned through 90 degrees so that the aperture will correspond in form with the plate. If the aperture for the lens is made through a piece of cork glued to the back of the box a very good fit is easily secured, and the result should then be as effective and as convenient as one could wish.

\* \* \*

#### Changing-Boxes in the Studio.

Most of the modern studio cameras are fitted with dark slides holding two, and in some cases four, plates, and it is often difficult for the operator with a troublesome child sitter, or a nervous adult, to be sure which was the last plate exposed. A number of single slides, each of which may be removed from the camera as soon as exposed and placed by themselves, solves the difficulty, but slides are expensive, and the cost of half a dozen or eight is no inconsiderable trifle. There is no reason why a good changing-box should not be used instead of dark slides. With landscape cameras the difficulty of register presents itself, the register having to correspond with that of the dark slides also used, necessitating a special arrangement for lifting the plate and inserting it in front of, or behind, the remainder. As portability is not so important in studio work, the register may be even as much as an inch, and the lifting of plates for changing is thus simplified. As soon as an exposure had been made the plate would be changed, and the question need never arise as to which plate was last exposed. A possible objection to the use of the changing-box is that holding twelve plates, it would not be convenient to develop an odd exposure or two while the sitter waited. If, however, the plates lifted from front to back the exposed plates would be readily accessible. Further, it is increasingly the practice to reserve development till the end of the day, it being found that much greater uniformity of negatives results when they are handled in batches than when the operator passes from the well-lighted studio to the dimly-lighted dark-room, and attempts to judge density by visual examination.

\* \* \*

#### Standard Flanges.

Years ago the thread on the lens and the corresponding thread of the flange were most usually of quite arbitrary size, and it was a very small chance that any lens would fit any other flange but its own. During the last ten or twelve years the standardisation of lens screw threads has made great progress. A large number of manufacturers have adopted the standard threads, and have so organised their workshops that such threads can be cut with a degree of accuracy enabling lenses to be screwed readily into any flange of the same size, yet to hold firmly. The convenience of this standardising is very considerable to the photographer, for it enables him to employ any of his lenses on any of his cameras, provided, naturally, that the lens is not too large or too heavy, and this by the aid of a few brass adapters which are not expensive luxuries.

The inconvenience of spare panels, and the necessity for cutting a circular opening in such before the lens can be attached for testing purposes, or for any work of an unusual character, is considerable. When contemplating the purchase of a new lens it may be well to note whether the screw thread is a standard one, in which case it will probably fit an existing flange or an adapter. Lenses which have odd-sized threads may readily have an adapter fitted, the outside screw of such adapter being the smallest possible standard screw. In this way, at a cost of two or three shillings, the convenient use of the lens is very greatly enhanced.

\* \* \*

#### The Efficiency of Diaphragm Shutters.

Mr. Chapman Jones draws attention in "Knowledge" to a point respecting the efficiency of diaphragm shutters that is, perhaps, not generally realised. It is that the higher the highest speed of the shutter, then, generally, the greater is its efficiency at lower exposures. For example, if we have two shutters, one with a highest speed of 1/100 sec., and the other with a highest speed of 1/200 sec., then, if both are set to 1/100 the latter shutter will be more efficient than the other by fifty per cent. The reason for this is very simple. The opening and closing of shutters of this type is effected by springs, and they are held open by a brake. If the speed of opening and closing is always the same, and variations in exposure are only made by keeping the brake on for a longer or shorter time, it is obvious that the higher the speed of opening and closing, the more efficient is the shutter. This speed fixes the shortest exposure that the shutter will give; therefore, the shorter the exposure the more efficient is the shutter. This is a matter often overlooked by those who study the efficiency of shutters from the mathematical point of view, without paying any regard to the details of the mechanism.

#### THE NEED FOR RESEARCH IN THE ACTION OF SILVER AND OTHER IMAGES ON BICHROMATE.

Processes that depend upon the hardening action of light on bichromated gelatine have long been of very great importance in photography, but of late years other methods of producing similar effects without the agency of light have been introduced, and though these newer methods are in very common use, we know little or nothing of the mechanism of the processes employed. Three important examples of these processes are Ozobrome, Bromoil, and Carbohydr. In all these bichromate is used, and it has therefore been assumed, somewhat hastily, that the final result is an image in bichromated gelatine similar to that produced by the agency of light. Though chromium compounds have been found to exist in the final image, and such a compound also exists in the light-affected image produced on bichromated gelatine, it does not follow that the compounds are the same, nor yet that their production by chemical action will necessarily harden the gelatine. A notable instance in which no hardening takes place is that of the process of intensification with chromium. In this case a silver image is bleached with a solution of potassium bichromate to which a few drops of hydrochloric acid have been added. If the acid is not in large excess a considerable quantity of a chromium compound is deposited in the image, but no hardening of the gelatine takes place.

The third of the three processes we have mentioned, Carbohydr, is essentially different from the other two. In it the gelatine is hardened by the application of a so-called "sensitising bath" of bichromate and alum, that

parently effects its purpose without producing any change in the silver image. In this case the silver is supposed to act as a catalyser, but in that of Ozobromol Bromoil it is clear that the action is not simply catalytic, for the silver is converted into a silver salt during the action of the hardening bath. The bleaching agent in the hardening bath is a mixture of potassium ferri-cyanide and potassium bromide, which is added to a solution of potassium bichromate, and the theory put forward to explain the result is that the ferrocyanide which is formed reduces the bichromate and so produces a chromium compound in the gelatine. This theory is plausible, but it depends rather obviously on the assumption that the gelatine will necessarily be hardened by a chemically reduced chromium compound, and it ignores, or, at any rate, does not account for, the fact that alum and other ingredients apparently aid the effect.

In bromoil the ozobromol solution is again used as a bleacher, but with the addition of an extra considerable quantity of alum, which addition appears to be necessary. The bleaching stage is followed by immersion in a 5 per cent. sulphuric acid bath, and this, from the theoretical point of view, is an interesting and important feature of the process. As all the chromium oxide compounds in the state of hydrates are readily soluble in mineral acids it naturally follows that this acid bath must remove a very large proportion of the chromium compound formed in the bleaching process. It is, in fact, obvious, from mere observation, that it does so, but nevertheless the gelatine in the image is not softened. This fact does not perhaps prove very much, seeing that a light-formed image of bichromated gelatine is not very materially softened by similar acid treatment. It appears, however, that the bromoil image is the more resistant of the two, and very usual testing reveals the important fact that the final bromoil image contains a considerable proportion of chromium compound. This is not the case in an image bleached by ferri-cyanide and bromide alone, and the fact that it is so with one bleached with those ingredients in the presence of bichromate points to some unfamiliar action that is not readily explained. Whether a similar compound exists in the ozobromol image is not yet clear. It is, of course, known that in certain circumstances gelatine is precipitated and hardened by ferrocyanic acid, but the matter is obscure. In considering the theory of bromoil and ozobromol, this is, however, one of the possi-

bilities to be looked for, while the action of the alum and of the organic acids generally used in the bleaching and hardening solutions must also be considered. The fact that a large excess of alum is essential to the bromoil process is certainly suggestive that it aids in the hardening process.

At present both the ozobromol and the bromoil processes are in the empiric stage. The methods employed are simply those that by dint of trial and repeated experiments have proved to be effective. The lack of any accurate knowledge of the theory prevents either process from being put on a sounder basis, and hinders the adoption of what might be valuable simplifications. A thorough investigation might lead to important improvements, and also suggest useful similar methods of producing images in hardened gelatine or other colloids.

Incidentally we have referred to the chromium compound produced in the gelatine as a hydrate, while every practical worker is familiar with the fact that the compound produced by light is brown in colour. This being so, it is curious that so many writers should refer to it as chromic oxide, which it obviously cannot be. Some Continental writers, we believe, have described it as chromic hydrate, but we do not know that they have actually identified it by analysis. As a matter of fact, it is very doubtful if simple chromic hydrate is formed at all. In the case of an image bleached with bichromate and hydrochloric acid the compound formed has been identified, as far as identification is apparently possible, with the mysterious brown hydrate called chromium tetroxide. This is only one out of a great variety of brown hydrates that no chemist knows very much about. Simple chromic hydrate, which is green, and not brown in colour, can be identified with certainty, but the others defy analysis, and it is a very open question whether some of them are not really salts of chromium. In these circumstances nothing is gained by jumping to conclusions and rashly classing the unknown products formed in the gelatine as chromic oxide. Some attempt should be made to isolate the product and to determine what known compound it is most nearly allied to.

It is obvious that the investigation of these processes is not a task to be attempted lightly, or one to be rushed through carelessly, but in our opinion it is a work that should be started without unnecessary delay, as it is clear that information of considerable photographic importance may be the result.

## DISTORTION IN SYMMETRICAL AND UNSYMMETRICAL PHOTOGRAPHIC OBJECTIVES.

DR. WANDERSLEB, of Jena, has undoubtedly earned the thanks of all those interested by the thorough and industrious manner in which he has graphically compared the distortion of sixty-four photographic lenses, his results being published in the *Zeitschrift für Instrumentenkunde*, 1907. But when he publishes his results in journals among whose readers will be found many of us, I may call the laity, a description of a portion of his work, in which he compares those unsymmetrical lenses which give the greatest freedom from distortion with symmetrical lenses which for the most part show distortion, it may disturb the minds of those already in possession of a symmetrical lens. In order to calm these fears and to place in a correct light the nature of the distortion given by symmetrical lenses, so that workers to whom practical results are of more importance than theory, may be able to properly judge the matter, I write these few lines.

At the outset I cannot agree with Dr. Wandersleb that the ab-

solute freedom from distortion of the symmetrical lens is a commonly acknowledged dogma. In those cases where an absolutely accurate representation comes into question, as in photogrammetry, the distortion of symmetrical lenses has long been known. I refer Dr. Wandersleb to a paper by Professor Dörge in the *"Photographischen Mitteilungen,"* 1886, in which the distortion of three lenses (Pantoscope, Euryscope, and Landscape Aplanat) are given, as well as to an article by Herr Bohlan in the *"Zeitschrift für Vermessungswesen,"* 1904, wherein results of tests of the Goerz Hypergon Double Anastigmat in truthful angular rendering were published.

Further, I attribute a greater importance than Dr. Wandersleb appears to do to the excellent work by Dr. M. von Rohr, *"Theorie und Geschichte des Photographischen Objectives,"* in which the orthoscopic conditions are dealt with. In my opinion, this book has done very much to explain the theory of photographic optics. I believe, therefore, Dr. Wandersleb's assertion that the

above-mentioned dogma is to-day generally acknowledged, proves his ignorance of the opinions held by the qualified optician, seeing that it has already for ten years past been proved to be not the case in reality.

As a proof of his assertion, Dr. Wandersleb publishes an extract from a book, the title of which he does not mention. The source not being named, the extract loses much of its force, and its value is still more diminished when it is known that the book referred to is "Das Objectiv im Dienste der Photographie," by Dr. E. Holm. Those acquainted with this book know that it was written entirely for practical workers, a point emphasised twice in the preface. Now, Dr. von Rohr writes in his book, page 53, "and one can rightly consider such symmetrical lenses

According to the sketch of Dr. Wandersleb, this lens draws a line, which passes through the middle of the plate, and which appears to him to be under 35 deg. of the optical axis, one hundredth-and-fiftieth too large. In the accompanying illustration, therefore, the chimney must, if it is to be absolutely accurate, be one two-hundredth-and-fiftieth of its height short. Dr. Wandersleb says that one can in practice easily see the result of the distortion; the perpendiculars of the house, for example, which may be at the edge of the plate, may be seen to have a very determined curvature. This statement is in contradiction to the extract given above from Dr. von Rohr.

In the accompanying illustration the perpendiculars of the house are, as Dr. Wandersleb desires, at the edge of the field,

as being practically free from distortion, through which the errors of the older optical system finds its explanation." When Dr. von Rohr in a work devoted to theory pens such a statement, then surely can Dr. Holm in a book written only for practical workers represent the symmetrical lens as being perfectly free from distortion.

How great is the distortion given by rapid symmetrical lenses? In any case so small that Dr. Wandersleb has to very strongly enlarge them in order merely to demonstrate them graphically. How it shows itself in practice shall here be shown, from an exposure made with a rapid symmetrical lens, the Goerz Dagor F.6.8.

I leave it to the reader to decide whether these lines show a "very determined curvature" or not.

Dr. Wandersleb's reproaches to those opticians who describe the symmetrical lens in their commercial literature as being free from distortion, are, in the light of the example just given, too weak for serious consideration. I may add that the C. P. Goerz Optical Works have already issued almost a quarter of a million symmetrical lenses, which are in use in all parts of the world, and up to the present they have never had a single complaint that one of the lenses showed distortion.

W. ZSCHOKKE,

Of the Scientific Staff of the C. P. Goerz Optical Works

**HACKNEY PHOTOGRAPHIC SOCIETY.**—The members of this society entertained their friends and each other on the occasion of their annual concert last week in their usual hearty manner, a special welcome being given to ladies. After a varied musical programme

had come to a conclusion, "The Man in Possession," a musical farce by Mr. Harold Lane, was introduced, and, as is not usual with that member of the community, obtained a hearty welcome, two of the leading parts being taken by Mr. Walter Selfe and his daughter.

## A NOTE ON THIOMOLYBDATE SULPHIDE-SUBSTITUTE IN SEPIA TONING.

The methods of "sulphide" toning being now in process of being improved by the provision of less odorous bodies than the sodium sulphide used as the darkening bath, the following further notes on one of the new compounds—thiomolybdate should be studied in conjunction with the instructions and formulæ of the inventor already given in our issue of October 25, 1907. Here Mr. Smith adds some further items from his experience.—Eds. "B.J."]

As mentioned in Watts' "Dictionary of Chemistry" that solutions of thiomolybdates when diluted, and especially in presence of free alkali, become turbid, and break up. Simple aqueous solutions of thiomolybdates certainly do not keep very well, and that reason in "The Photographic Journal," October, 1907, page 361, I did not recommend that a dilute solution of ammonium thiomolybdate should be kept for long. In "Watts," however, no time is mentioned in which the decomposition of these solutions take place.

In Fremy's "Encyclopédie" it is stated that dilute solutions of thiomolybdates, if neutral, decompose very slowly if exposed to the air. Concentrated solutions keep well in the air. Dilute solutions gradually decompose, but the changes take a long time.

Considerable experience with these solutions has shown me that (somewhat contrary to the statement in "Watts") dilute solutions of ammonium thiomolybdate  $(\text{NH}_4)_2 \text{MoS}_4$  for example, keep extremely well when made alkaline with their own alkali, in this case, of course, ammonia. For instance, a toning solution of 60 minims of a 1 per cent. solution of  $(\text{NH}_4)_2 \text{MoS}_4$ , one ounce of water, made alkaline with five minims of .380 ammonia, after being kept for six weeks in full daylight in a white glass loosely-stoppered bottle, half full of the solution, and a bleached bromide print sepia satisfactorily. After toning, this solution was replaced in the bottle, and again kept in full daylight for seven weeks, when it was again tested for toning properties. By this time (over three months) this very toning solution had become somewhat decomposed; and while, allowing it plenty of time (about twenty minutes), it still toned a bleached print a good sepia colour, towards the end of the toning the shadows of the print became toned with a bright silvery metallic deposit, which was not apparently a sulphide of molybdenum, but presumably the metal itself.

I have noticed this metallic deposit before, when toning with stale dilute thiomolybdate solutions to which no ammonia had been added at the time of making up. The tendency in the absence of ammonia was for the metallic deposit to be of a golden yellow colour, and I noticed the same effect on a piece of bright silver immersed in the solution. However, this metallic deposit does not appear to be of any immediate interest, but I think that the fact that such very dilute solutions of this type of thiomolybdate, when alkaline, keep so well as regards their toning properties, is of interest, since, as one would naturally expect, I find that reasonably concentrated solutions made alkaline in this way, keep excellently.

As regards freedom from odour, one can hardly call such solutions odourless, since they smell of ammonia. However, in using an alkaline toning solution of this type the odour of sulphuretted hydrogen is practically negligible; in fact, there is no free sulphuretted hydrogen. A concentrated alkaline solution of this sort seems preferable to the pure crystals as regards freedom from odour, as, unless very freshly prepared, the crystals are apt to give off sufficient smell of, first ammonia, and afterwards sulphuretted hydrogen, to be quite in evidence on opening the bottle, though on dissolving the crystals to form a toning solution with ammonia the sulphuretted hydrogen is difficult to detect.

Oxygen from the air is presumably the prime factor in the decomposition of thiomolybdate solutions, since other re-agents will apparently retard decomposition, such as sodium sulphite, which appears to act in much the same way as it does with organic developers. Metabisulphites, however seem to break up thiomolybdates with some rapidity. A 1 per cent. solution of ammonium thiomolybdate with sodium sulphite, kept in a loosely-corked test-tube, at the end of three months well retained its orange-red colour though a little sulphuretted hydrogen could be detected on removing the cork. H. E. SMITH.

## PRACTICAL PLATINOTYPE.

"Variations in platinotype" formed the title of a thoroughly practical and exhaustive demonstration given by Mr. W. H. Smith at the Croydon Camera Club on the 5th inst. Apart from the ordinary procedure, more or less familiar, several points were dealt with which, in practice, might be overlooked, and therefore may be usefully recorded.—Eds. "B.J."]

In opening his remarks, Mr. Smith said that, to obtain the very best results, no doubt, a good negative was essential; an observation applicable to all processes, though perhaps a little more so with platinotype than with others. This fact, however, was soon hurled at him by way of reproach, and was significant, as it clearly showed that the average amateur photographer too frequently realised his inability to produce other than second-grade work. Perhaps the art of "faking" and dodging, which they had heard so much about at the Croydon Camera Club recently, was partly responsible for this. An enthusiastic operator thought nothing of spending hours in manipulating negative and print to produce a result which in many cases might, either whole or in part, have been obtained in the first instance. He suggested that some of this superfluous energy might be usefully expended in trying to produce a better negative to start with. Compared with gum-bichromate and similar processes,

platinotype could not be said to be suitable for many modern pictorialists; it was, on the other hand, eminently suitable for a good "pictorial negative."

### Sundry Misconceptions.

A complaint occasionally made was that platinotype papers were dear. He dissented. They were expensive, doubtless, and so were gold and metallic platinum. Still another grumble he had encountered viz., that winter-time was unsuitable for platinotype printing. The reverse was the case, and obviously so; at 62 deg. Fahr. the water vapour in the air, when saturated, was nearly three times greater than at freezing point. In cold weather, if the room in which the prints were loaded had a fire in it, so that its temperature was above that outside, then the air in the room had a distinct drying action. In this connection, under certain conditions, air at 32 deg. Fahr. might be heated

to 62 deg., and such a degree of dryness obtained as to be intolerable to the human frame. Care should be taken that the negative and rubber-pad be quite dry, and the sensitive paper, being then isolated from moisture, might be exposed all day without detriment. On the other hand, a damp hot summer's day was the most dangerous of all. This "bogey" was in a large measure a relic of the past, for fifteen years ago the paper was undoubtedly very much affected by damp. In those days it would only keep three months or so, now its keeping properties were considerable, and paper that would keep longer always stood damp better. At no time, however, was there any necessity to expose the paper needlessly to the action of the air.

#### The "Glycerine" Method.

Mr. Smith at this stage developed several prints of the respectable size of 36 by 20 inches and downwards with a glycerined developer, and pointed out that dishes the size of the print were not essential: a smaller dish would do, provided it was a little longer than the prints were broad. Such prints might be developed by passing them through the developer, and then carefully doubling them over, to allow of insertion in the clearing and washing baths. Sometimes, in text-books and articles on glycerine development, it was recommended to slow down the action by the addition of a certain proportion of water to the glycerine and developer. This was a mistake; if protracted action was desired, this should be controlled by the proportion of glycerine. A good normal developer would be equal parts of a saturated solution of oxalate of potash with addition of oxalic acid and glycerine. He also cautioned his hearers against local acceleration of the image by the application of *plain* developer. This might cause a distinct difference in tone. The better plan to adopt was to keep back those parts requiring suppression, by gently removing the developer with a piece of clean cambric or other material, followed, if necessary, by the application of pure glycerine; the other portions of the print would then slowly gain in intensity until the right effect was obtained.

#### Discussion.

The President, Mr. J. M. Sellors, an old platinotype worker, said he could confirm Mr. Smith's observations as regards the "bogey of damp." Only the other day, owing to the badness of the light, and the density of the particular negative, he had a frame out for a week; the platinotype print showed no ill effects. Occasionally he had troubles with bubbles, which left recording marks behind them; he had also now and then found markings due to the platinum black washing away.

Mr. S. H. Wratten said he had found the Japine paper most useful, "and now used no other"; the power to render increased contrast by the addition of glycerine had enabled him to obtain

satisfactory prints from negatives which were too thin to be adequately rendered by any other process. He, too, at intervals had been troubled with stains due to platinum black coming away. In one case, that of a print from a negative taken on an "ordinary" plate, rendering the sky in the print as an expanse of white paper, some black hats against a clear sky radiating platinum black.

Mr. Terry warned beginners against attempting to remove a bubble by an application of a finger wet after immersion in an acid bath. The result was not pleasing.

Dr. Mees, referring to an observation of Mr. Smith's earlier in the evening, "that the knack of judging the depth of the image was easily acquired," asked the lecturer whether he had personally printed the platinotype pictures before them, and also inquired whether Mr. Smith could give an indication as to what exposure would be required for enlarging two diameters on platinotype paper by means of an arc lamp.

Mr. Dollond said he should regard with pleasure an even tone on toning platinotype prints. Years ago, when he worked on his formula for toning platinotypes with gold he invariably found it certain and regular in its action. Latterly uniform results were not obtained, and he inquired the reason.

Mr. Smith, in reply, said that as regards "bubbles," a little care would prevent these occurring; if they did, however, they should be immediately touched with the finger, when, in some cases, they would disappear without leaving any mark behind, in other cases the contrary would prevail.

As to the pigment washing off and causing markings, the latter feature was entirely due to errors in manipulation. If a print was floated, and then picked up and examined in the hand, the developer would flow off in lines, and the possibility of staining by platinum black arose. The proper course was to float the print, and when down give a slight wriggling motion to the next to lift one end of the print, and then the other, to see if any bubbles had been formed; if so, they should be at once moved, and the print allowed to fall back on the surface of the developer. If the print was only raised for a short time there was no danger of the pigment running and adhering to the paper. In reference to Dr. Mees' questions, he had not personally printed the specimens developed, but he had been in the habit at that time of printing hundreds of platinotypes each day. As to enlarging direct; under the conditions stated, twenty minutes would be about right; a good deal, of course, depended upon the power of the arc and the density of the negative. In reply to Mr. Dollond, Mr. Smith said that the toning action of gold possibly depended upon a minute trace of iron incorporated with the image. A thorough clearing in the acid baths would probably render toning by this method more difficult. Mr. Dollond's formula, in consequence, might form a good test for any residual iron.

## THE EXHIBITION OF THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

We much regret that our critic, by the merest oversight, omitted to refer to the works of Mr. Fellows Willson, when reviewing the exhibition of the Professional Photographers' Association. Mr. Fellows Willson himself, as well as the numerous admirers of his work, will not need our assurances that photographic portraits such as these are highly esteemed by our critic. He particularly admires the fine head and shoulders of the gentleman's portrait, though the reflected light is, in his opinion, a thought too bright upon the collar. Three ovals with borders, in the miniature frame pattern, contain charming heads of young ladies, while the "placing" and filling of the oval space is tastefully managed. A Court dress piece and a

theatrical portrait show Mr. Fellows Willson's manner of giving grace to a figure, and keeping the uttermost stitch of silk and satin well displayed.

From the Press notices of the exhibitions which have appeared, we may quote the following: The "Times" says: "One has only to recall the character of the prints with which the now almost extinct portrait album was furnished to realise to how great an extent the example set by the more accomplished amateurs in photography has influenced the work of their professional contemporaries. The highly polished and too intensely vivid representation of stiff and awkwardly posed people which satisfied a quarter of a century ago, and doubtless still produced in places where public taste is less fastidious."

us; but there is reason to be grateful that there are photographers such as Alfred Ellis, Martin Jacquette, and that famous photographer of Royalties, William Downey, to mention three represented in the present exhibition, who can produce realistic likenesses which possess more than a little of the idealisation of the portrait painter. There are also shown several examples of the work of Mr. Fellows Willson, all of which exhibit creditable craftsmanship; but perhaps the first place must be given to the work of Messrs. Drummond, Young and Watson, of Edinburgh. Miss Wall Smith, who is the only lady exhibitor, shows some powerful clever work."

The "Morning Post" writes:—"The amateur may get hints from

it as to the most effective manner of posing and lighting a model; the professional will furthermore learn much by studying the style and the mannerism of several of the leading portrait photographers; while those who are merely interested in photography as customers may find the exhibition—to which entrance is obtainable free of charge—useful in helping them to choose a firm which turns out likenesses in accordance with their notions of what is approvable. For instance, there are the 'catchy' picture portraits of Messrs. Ellis and Walery, the engraving-like presentation plates of Mr. Mendelssohn, and the dainty and fanciful little prints of Messrs. Young and Watson, with many more of equal distinction to engage attention."

## ORTHOCHROMATISM BY BATHING.—A SENSITOMETRIC STUDY.

The following is the full text of a further communication in the series of researches by Mr. R. J. Wallace, of the Yerkes Observatory, appearing as "Studies in Sensitometry." The same author's first published experiments on a system of daylight sensitometry appeared last year, and were reprinted in our columns from proofs specially prepared, as was the present paper, by Mr. Wallace, for "The British Journal of Photography." Our acknowledgments are therefore equally due to Mr. Wallace and to the "Astrophysical Journal," in which the papers have first appeared.—Eds., "B.J."]

### III.

*Pinacyanol + pinaverdol + homoccol.*—This combination, when made in an aqueous ammoniacal bath and without supplementary washing, sensitises a "27" plate for practically the entire visible spectrum, extending easily to  $\lambda$  7,200. The usual gap in the blue-green is entirely closed and the curve is fairly smooth throughout. Wash the plate in water after staining, although increasing the speed, does not add anything to the chromatic value of the plate; a slight improvement is effected by an alcohol washing-bath. If the dye is made up with alcohol+ammonia the sensitising action is weak and ill-defined, and possesses no value whatever.

The staining-bath be made up with dilute ethyl alcohol and ammonia we obtain a most excellent plate, with a markedly high sensitiveness and evenness of action. A brief washing in alcohol seems to be also very beneficial, no apparent difference being (after exposure and development) whether this washing be continued for 20 seconds or 5 minutes.

If all results obtained, this plate is decidedly the best, and for evenness of working and general freedom from fog it leaves little to be desired. The bathing formula is as follows:—

Pinacyanol	1:1000	50 minims
Pinaverdol	1:1000	40 minims
Homoccol	1:1000	40 minims
Ammonia		120 minims
Alcohol		3 oz.
Water		4 oz.

Exposure time 4 minutes; alcohol washing 20 seconds.

Fig. 7.

Fig. 7 shows the measured curve of this plate together with two under-exposure curves showing the relative chromatic effect with

reduced exposures; development, of course, remaining constant. Speed dif. = 0.17.

TYPE 124. 11. x

$\lambda$	6800	6300	5900	5500	5100
Exposure					
Normal .....	1.51	1.26	1.24	1.18	1.09
A .....	4.72	1.65	1.80	1.45	1.29
B .....	8.75	2.42	2.41	1.92	1.43

Speed difference = 13 p.c. in favour of the "27."

*Pinacyanol + pinaverdol + dicyanine* in ammoniacal water bath gives also a very good plate, although the cation of the dicyanine seems to reduce greatly the general integral sensitiveness.<sup>21</sup> The blue-green insensitive gap is closed and the chromatic sensitiveness-curve descends toward the red in a good flowing sweep, the action extending to  $\lambda$  7,200 with normal exposure but may easily be forced below Fraunhofer's A; on several plates the action is carried distinctly lower than  $\lambda$  8,400. Washing does not appear to influence the selective action in any way.

When the plate is treated to conform to .11 the sensitiveness to the red at  $\lambda$  6,500 and to the green at  $\lambda$  5,700 is increased, which

Fig. 8.

adds materially to the value of the plate in general, although this increase is at the expense of the blue-green, which loses somewhat

<sup>21</sup> This lowering of the general plate sensitiveness is noticed and commented upon by Monpillard, *Bull. Soc. Franc. Phot.* (2), 22, 1906; also *Journ. Roy. Phot. Soc.* 46, 261, 1906.

in sensitiveness. The plate works clean and bright, but does not keep. For sensitiveness-curve see Fig. 8. Speed dif.=1.64.

Type 125.11.					
At $\lambda = 6800$	6300	5900	5500	5100	
$\chi = 4.72$	3.07	2.00	1.76	1.49	

The bath formula was as follows:—

Pinacyanol	1:1000	30 minims
Pinaverdol	1:1000	60 minims
Dicyanine	1:1000	40 minims
Ammonia		120 minims
Alcohol		3 oz.
Water		4 oz.

Bathing-time—3 minutes; washing-time—30 seconds; temperature—23 deg. C.

silver salts, but subsequent experiments seem to point instead to the action of the combined dyes as being the main factor influencing the reduction. This opinion must, however, be accepted with reserve, as sufficient work was not performed to confirm it, the type not being in direct line with the object sought.

The normal sensitiveness extends to  $\lambda$  7200, although with a slight increase of exposure the great A group is clearly improved. The plate is foggy if kept over a few days, and must therefore be used immediately after preparation. A continued water wash after bathing gives a cleaner and better keeping plate, but considerably reduces the speed. It may be mentioned that if the dye bath is made up with an aqueous ammoniacal solution (.7) and the plate be washed after bathing, the same lowering of  $\gamma\omega\beta$  may be observed. Speed dif.=0.62.

TABLE II,  
Values of  $\chi = \frac{D\beta}{D\lambda_n}$

Type.	Dyestuffs.	At $\lambda$ 6800	At $\lambda$ 6300	At $\lambda$ 5900	At $\lambda$ 5500	At $\lambda$ 5100	Sensitiveness Limit (Normal Exposure)	Speed Reduction.

Table II. contains the  $\chi$  values for the remaining plates of interest.

#### Commercial Bathed Plates.

Wratten "spectrum panchromatic."<sup>22</sup>—The consideration of orthochromatism by methods of bathing would be incomplete without notice of this comparatively recent addition to the commercial plate-market. Undoubtedly, to the individual without previous experience in plate-bathing there is a certain amount of technical skill required for the

<sup>22</sup> Wratten and Wainwright, Ltd., Croydon, Surrey, England.

successful production of bathed plates of uniform quality. Besides, there is the question of necessary accommodations, such as bathing-tubs and drying-cabinet, which very often prevent the taking-up of work, more particularly by the individual who has only occasional use for such a product.

It is with the purpose of meeting just such conditions that these plates are prepared, and as they are bathed plates, it is proper that their consideration should find a place here.

These panchromatic plates are made in two grades: "fast" and "slow," and from a series of spectrum exposures, handled in precisely

Fig. 9.

In the same manner as the plates previously referred to, a series of measurements was made from which were plotted the curves shown in Fig. 9.<sup>23</sup>

#### X FOR WRATTEN "PANCHROMATIC."

Type.	At $\lambda$ 6800	6300	5000	5500	5100
Fast .....	11.6	4.80	3.30	2.12	1.47
Slow .....	2.41	1.37	1.42	1.42	1.5

When reasonably fresh, the "fast" grade works with vigour and brilliancy, together with good freedom from fog; but, like all bathed plates, suffers deterioration as it is kept. The sensitiveness is good, and at normal exposure pursues a fairly smooth curve extending beyond  $\lambda$  6870; with increased exposure to beyond  $\lambda$  7200. A normally exposed plate shows three distinct maxima, situated at  $\lambda$  6150,  $\lambda$  4850, and  $\lambda$  6400. The slow panchromatic is characterised by a remarkably low  $\gamma \propto \beta$ . There is somewhat of a drop in the blue-violet from  $\lambda$  4360-5150, but from that point the curve rises with great evenness to  $\lambda$  6500, whence it continues with gradually varying sensitiveness on to about  $\lambda$  7500. A is obtained with increased exposure. Unquestionably these are the finest panchromatic plates at present commercially obtainable, and the scientist or three-colour worker who cannot prepare his own plates is certainly greatly indebted for the enterprise manifested by their production. The inclusion here of their curves of spectral sensitiveness is necessary for purposes of direct comparison with other types under identical conditions.<sup>24</sup>

From the foregoing description and curves it will be seen that by the best approximation to isochromatism is obtained in type "A.11." Further observation upon the behaviour of the plate after a long time shows that it follows the general rule by suffering a decline in relative chromatic sensitiveness as its age increases. This retrograde action, however, is but slight for the first period (extending over several weeks), although distinctly noticeable after the lapse of a few months. Measurement of a plate bathed at the same time as that

plotted in Fig. 7, but kept for 60 days before exposure, shows a  $\chi$ -difference as follows:—

At $\lambda$ = 6800	6300	5900	5500	5100
$\Delta\chi$ = 3.09	0.39	.56	.25	.03

from which it follows that in order to obtain the very best effect the plates should be used when fresh.<sup>25</sup>

#### Compensation Filter.

While the curve shown in Fig. 7 represents the best approximation to a true isochromatic value by means of the judicious selection of plate and dye bath, yet to be absolutely correct this curve should be a straight horizontal line. The advantages of a plate possessing such a curve of sensitiveness to those engaged in recording scientific data is sufficiently evident without detailed exposition. To approach this straight-line condition two courses are open: (1) the introduction to the film of a chemically inert dye, whose function consists in staining the gelatine and thus acting as a colour filter; or (2) the use of a separate colour-filter in the path of the incident light. This latter is (for the present purpose) decidedly the better method, because in the former case the integral speed of the plate is considerably lowered.

Fig. 10.

Repeating in Fig. 10 the sensitiveness-curve of Fig. 7, and drawing the horizontal path of the new (desired) sensitiveness-curve, we may obtain the extinction coefficient-curve of the colour-filter necessary, by means of the simple formula

$$\frac{D-c}{\gamma} = e,$$

where  $D$  = density of the plate at any given wave-length,  $c$  = the proposed new curve of sensitiveness,  $\gamma$  = the development factor, and  $e$  = the extinction-co-efficient of the filter sought. As  $c$  in this instance is represented by a perfectly horizontal line, it is therefore sufficient to accept everything above that line as an absorption record of the filter required, if we now consider  $c$  as representing zero density.<sup>26</sup>

In the dye tartrazine we obtain the best agent for the selective absorption of the excessive density in the blue-violet; and ultra-violet as far as  $\lambda$  3300, which is practically the limit of glass transmission. A spectrum photograph through an adjusted solution of this dye still leaves much to be desired with reference to the red end, the drop at  $\lambda$  6200 being quite apparent; this is, however, considerably improved by the introduction to the filter of a very small amount of naphthylamine brown.

The best proportionate strength of solution yet arrived at is

A. Tartrazine	0.1 gram.
Water	100.0 cc.
B. Naphthylamine Brown	0.01 gram.
Water	100.0 cc.

Compensation filter = A. 10 cc.  
Water 120 cc.

B. 40.0 cc. in a thickness of 5 mm.

The new curve of sensitiveness is shown in Fig. 10. The intro-

<sup>23</sup> The writer here desires to express his thanks and appreciation to Dr. Mees, who courteously presented the plates.

<sup>24</sup> The curve of the "fast" panchromatic, together with the  $\chi$  value for the same, is comparable with that plotted by Mees (*Brit. Jour. Phot.*, 53, 430, 1906), but on  $\lambda$  4700 to the limit of the red-sensitiveness. Owing (presumably) to the course, Mees' curve does not represent the true point of maximum sensitiveness, which should be at  $\lambda$  4150 instead of  $\lambda$  4700, the usual maximum for *AgBr*.

<sup>25</sup> For several months past this plate has been in almost constant use at this observatory in the records for the photographic photometry of coloured variables, with results in every way satisfactory.

<sup>26</sup> In an able paper by André Callier the function and preparation of colour-filters is very exhaustively treated, but while the methods and ideas therein expressed are deserving of the highest commendation, yet it must not be lost sight of that some of the curves and measurements are of prismatic spectra.—A. Callier, "Ecrans colorés," *Revue des sciences photographiques*, No. 10, 1906.

duction of this filter, however, increases the exposure time by the factor  $\times 2.2$ . For solar or laboratory absorption spectra this increase is a matter of no consequence. With bright-line emission spectra the use of the filter is unnecessary.

ROBERT JAMES WALLACE.

#### PHOTOGRAPHIC COPIES OF UNPUBLISHED ADVERTISEMENT PICTURES.

A CASE heard before Mr. Justice Swinfen Eady in the Chancery Division of the High Courts, on January 20 and 21, was concluded last week, when the reserved judgment was delivered. The parties to the action were Mansell (plaintiff) and the Valley Printing Company and Rankine (defendants). The case contains elements which relate it to many others liable to occur in the illustrative trades, and we therefore quote extensively from the judgment of the learned judge as reported in the *Times* of February 7.

The action was for damages for infringement of the plaintiff's common law right of property in unpublished pictures. The pictures had been copied by an employee who sold the copies as his own to a firm of printers, and they in good faith published them.

Mr. Justice Swinfen Eady read the following judgment:—The plaintiff is an artists' colour and general printer and publisher, and for the purpose of his business he employs artists to make for him pictures and designs suitable for use as artistic advertisements. The exclusive property in all these pictures and designs is in the plaintiff, and they are produced by persons in his employ, to whom he pays regular weekly wages. The plaintiff usually retains the copyright in these, after publication, and makes a profit by printing in colour from them for use in various methods of advertisement. Sometimes he sells the copyright outright, usually, as one of the terms of sale, obtaining the order for the printing. Amongst other employees, he had in his service between 1902 and 1905 a Mr. Higham, who received a salary of £8 a week and a bonus, and the defendant Rankine, who was latterly paid £3 a week. Amongst the pictures and designs made by Higham for the plaintiff were three of those mentioned in the statement of claim, namely, "Three figures walking" (No. 3); "A girl in summer dress with roses in large fancy hat" (No. 4); and "A head and shoulders in large fancy hat" (No. 5). The other three pictures mentioned in the statement of claim were withdrawn during the hearing for various reasons and need not be further considered. None of the three drawings numbered 3, 4, and 5 have ever been published by the plaintiff, and until the matters complained of they were entirely unpublished. The defendant D. H. Rankine left the plaintiff's employ in July, 1905. He subsequently sold to the Valley Printing Company certain drawings; and the question is whether three of these drawings are copies or colourable imitations of Higham's three drawings in question, owned by the plaintiff.

The matter was brought to the plaintiff's notice in this way. A representative of Dent and Co., Limited, engravers and etchers, called on the plaintiff and submitted to him as a specimen of their work a proof of a design, and the plaintiff immediately recognised in the proof, or thought he did, a colourable imitation of his drawing No. 5. Inquiries led to the information that the work had been done by Dent and Co., Limited, for the Valley Printing Company. The plaintiff went to their offices, and immediately recognised on their premises other drawings which he considered were copies or colourable imitations of other drawings of Higham's which belonged to himself. Mr. Oliver Pearce, who carries on business as a fashion printer, under the style of the Valley Printing Company, at Cleckheaton, in Yorkshire, and in London, gave to the plaintiff every information and assistance, and said that he had purchased the drawings from a Mr. D. S. Hay, who lived near Diss, in Norfolk. The plaintiff described the appearance of the defendant Rankine to Mr. Pearce, and the latter said "That fits the artist named Hay from whom I bought the drawings"; whereupon the plaintiff said, "Your Hay is my Rankine." The plaintiff then went to Diss, with his manager, Mr. Simms, saw the defendant Rankine and his wife, and, according to the plaintiff's evidence, Rankine made a confession of what he had done, and asked for forgiveness. He ultimately allowed the plaintiff to examine a portfolio in his studio, where the plaintiff found some fifty photographs of Higham's drawings and pictures belonging to the plaintiff, including two of those now in question, and also two original drawings of Higham's belonging to

the plaintiff, and three tracings of Higham's drawings. All these were taken away by the plaintiff with Rankine's consent. . . . It is clear that Rankine, while in the plaintiff's employ, in an underhand manner, during the dinner hour, when the other employees were absent from the plaintiff's studio, surreptitiously made photographs of Higham's drawings. . . . I am clearly of opinion that the three drawings Nos. 3, 4, and 5 are copies or colourable imitations of the plaintiff's three drawings. . . . The defendant Rankine did not deny—that is really only too obvious—that he used his surreptitious materials to assist him in his drawings, but he alleged that he did not "actually copy" Higham's drawings, only took suggestions from them. In my opinion Rankine's Nos. 3, 4, and 5 are copies or colourable imitations of plaintiff's Nos. 3, 4, and 5; but no damages are claimed in respect of No. 3, as that has not been published by the Valley Printing Company. Nos. 4 and 5 have been published, and the damage which the plaintiff has sustained is the loss of what these drawings cost him—as to No. 4, £18, and as to No. 5, £25, making together £43.

The value of these drawings for advertising purposes lies in their originality, and it appears by the evidence that after a drawing or any copy or colourable imitation of it, has once been published the value of it for advertising purposes is destroyed; it will be quite impossible for the plaintiff in the future to deal with their No. 3, or No. 5 as original and unpublished drawings. There must, therefore, be an injunction as prayed against the defendant Rankine with £43 damages and costs.

With regard to the Valley Printing Company, it was contended that they were affected with notice that the designs had been improperly obtained by Rankine. This contention failed, and, indeed, was not persisted in at the end. The only ground put forward in support of it was an alleged insufficient price paid to Rankine for the drawings, but on the evidence this wholly failed. I am quite satisfied that the Valley Printing Company acted in good faith from beginning to end; they acquired the drawings in the ordinary way of business, and paid full value for them; they dealt with Rankine under the name of D. S. Hay, believing that to be his real name when they were approached by the plaintiff they at once gave all the information in their power, showed the plaintiff all the drawings of Rankine's which they had, and, when they learnt the circumstances, agreed not to make any further use, not only of the drawings complained of, but of any further drawings of Rankine's which they had; and I deal with the case, so far as they are concerned, upon the footing that they are innocent parties. They have, however, converted to their own use (although innocently) the property of another. It was insisted on their behalf that, having acted innocently, and not having taken any physical thing belonging to the plaintiff, they were not under any liability for damages; and it was urged that no authority whatever could be produced in support of the proposition that they were under any legal liability for what they had done.

The present case is not one of copyright, which is statutory, and arises upon publication; the plaintiff has an undoubted right of property at common law. As Lord St. Leonards pointed out in "*Jefferys v. Boosey*" (1854, 4 H. L. Cas., at p. 979), nothing can be more distinct than these two things. He said: "The common law does give a man who has composed a work a right to that composition, just as he has a right to any other part of his personal property; but the question of the right of excluding all the world from copying, and of himself claiming the exclusive right of forever copying his own composition, after he has published it to the world, is a totally different thing." Lord Brougham also pointed out (at p. 962) that the right of the author before publication was unquestioned. Mr. Justice Erle, in giving his opinion upon the question submitted to the judges, stated what that right was. He said (p. 867): "The nature of the right of an author in his works is analogous to the rights of ownership in other personal property, and is far more extensive than the control of copying after publication in print, which is the limited meaning of copyright in its common acceptance, and which is the right of an author, to which the statute of Anne relates. Thus, if after composition the author chooses to keep his writings private, he has the remedies for wrongful abstraction of copies analogous to those of an owner of personal property in the like case. He may prevent publication; he may require back the copies wrongfully made; he may sue for damages

any are sustained." Now, the remedies "of an owner of personality in the like case" are clear and well-established. Any person who, however innocently, obtains possession of the goods of a person who has been fraudulently deprived of them, and disposes of them, whether for his own benefit or that of any other person, is guilty of a conversion. See "*Hollins v. Fowler*" (1874, L.R. 9 H.L., 757, 795).

So far as regards the common law right of property in unpublished works, no distinction can be drawn between a literary work and an artistic work. "The property," said Lord Cottenham in "*Prince v. Newitt*" (1849, 1 Mac. and G., at p. 42), "of an author or composer of any work, whether of literature, art, or science, in which work unpublished and kept for his private use or pleasure, cannot be disputed after the many decisions in which that proposition has been affirmed or assumed." And on the final hearing of the same case Vice-Chancellor Knight Bruce said (2 De G. and J., at pp. 695, 696): "Upon the principle, therefore, of protecting property, it is that the common law, in cases not aided nor prejudiced by statute, shelters the privacy and seclusion of thoughts and sentiments committed to writing, and desired by the author to remain not generally known. . . . Such, then, being, as I believe, the nature and foundation of the common law as to manuscripts, independently of Parliamentary additions and subtractions, its operation cannot of necessity be confined to literary subjects. That would be to limit the rule by the example. Wherever the produce of labour is liable to invasion in an analogous manner, there must, I propose, be a title to analogous protection or redress." The right of an author of an unpublished literary production or work of art not confined to the paper or canvas or other material upon which the work is written or placed. His right is an exclusive right to publish or refrain from publishing it, as he may please, and anyone who publishes it without his consent infringes his legal right, and the act which is actionable *per se*. It matters not how the wronger obtained the production which he publishes, whether he took away the author's original material, or whether he only copied it, or whether some third person copied it and passed the copy on to him. In "*Miller v. Taylor*" (1769, 4 Burr., 2,303) the question determined was as to the existence of any common law right of property, after publication by the author, and after the expiration of the statutory period of copyright under the Act of Parliament (Ann., c. 19. The effect of the decision of the Court of King's Bench in that case was afterwards reversed by the House of Lords in "*Donaldsons v. Beckett*" (1774, 4 Burr., 2,408), which decided that after due publication, and the expiration of the statutory copyright, the author's sole right of printing and publishing is at an end. But in both those cases the nature of the common law right before publication and the remedy for the violation of that right were considered. In the former case Lord Mansfield, at p. 2,396, stated that the common law right in unpublished works was "equally detached from the manuscript or any other physical distance whatsoever"; that the common law right was violated by another person printing it without the author's consent; and that the proper remedy was by an action on the case for damages. In "*Donaldsons v. Beckett*" (*ubi supra*) the question was raised whether an innocent violation of the common law right would give rise to an action for damages. The Judges were directed by the House of Lords to give their opinion upon five questions, of which the first was: "Whether at common law an author of any book or literary composition had the sole right of first printing and publishing the same for sale, and might bring an action against any person who printed, published, and sold the same without his consent?" Of the twelve Judges, eleven gave a formal opinion, and eight of them, including the Lord Chief Justice of the Common Pleas and the Lord Chief Baron, answered the question so put in the affirmative; two of them (Mr. Baron Perrott and Mr. Baron Alderson) answered the question by saying that at common law an author had the sole right as mentioned, but could not bring an action against any person who printed, published, and sold the same, unless such person obtained the copy by fraud or violence; and one Judge (Mr. Baron Eyre) answered the first question in the negative. The remaining Judge was Lord Mansfield, and it appears from "*Burr.*, 2,417, that Lord Mansfield concurred with the eight Judges in the first question. The result, therefore, was that, in the opinion of nine of the twelve Judges, an action lay for the infringement of

the common law right against a person who infringed although innocently and without any fraud or violence. This view was acted upon by the Court of Exchequer in 1862. In "*Mayall v. Higby*" (1 H. and C., 148), the defendant was the innocent purchaser of some unpublished photographs belonging to the plaintiff, and which the vendors were not entitled to sell to the defendant. The defendant took fresh negatives of these photographs, and printed from the negatives so obtained. The plaintiff at the trial obtained not only judgment for the return of the photographs or payment of their value, but also 40s. damages for the injury done to him by taking the copies, and an injunction restraining the defendant from selling the copies so obtained and from making any more. The Court of Exchequer upheld the judgment, the Lord Chief Baron stating that the 40s. damages were in respect of the infringement of the plaintiff's right. Baron Bramwell pointed out during the course of the argument that the wrongful act of which the plaintiff complained was a compound one—namely, copying the plaintiff's works and selling the copies. Thus the defendant who had innocently invaded the plaintiff's right by making copies of unpublished photographs, and by publishing and selling the copies so made, was held liable to damages for the invasion of the plaintiff's rights.

In the present case the plaintiff has, in my opinion, a right to recover against the defendants, the Valley Printing Company, although those defendants have not converted anything physical belonging to the plaintiff, and although they have acted innocently. The plaintiff, therefore, recovers judgment against the Valley Printing Company as well as against the defendant Rankine for £43 damages. With regard to the costs, the plaintiff raised against the Valley Printing Company an issue upon which he failed—namely, he alleged that those defendants acquired the pictures with knowledge that the same had been improperly obtained by the defendant Rankine. Although this allegation was not persisted in to the end, the Valley Printing Company were brought into court to defend it, and are entitled to be relieved in respect of it from some portion of the costs of the action. The proper course will be to let the plaintiff's costs be taxed, and let him recover two-thirds of the amount against the Valley Printing Company. There will be an order for delivery up to the plaintiff on oath of all copies and colourable imitations (if any) of his pictures and designs in the defendants' possession.

## Exhibitions.

### LONDON PICTURES.

When one considers the altogether unique effects that London presents, the wonder is great that artists living in the midst of its varied charms do not more often make it the theme of their pictorial efforts. No place on earth is exactly like it. All other large towns at home and abroad are large towns. London is a world. Foreign artists have fallen before its fascination more frequently, perhaps, than have English painters. Possibly they are on the look out, and are receptive by intention, whilst the native is callous as to what has been his everyday environment from infancy. Nevertheless, one would think that the stately massiveness of a Thames bridge, swarming with traffic, under the glare of sunlight, need not have waited for Pissarro's eye and hand.

There have been plenty of London sketchers making pretty drawings of "old bits," "quaint bits," and so on; but that is not seizing the spirit of unique London. Paris or Nuremberg would furnish better hunting grounds for such subjects. Latterly one or two talented men have caught the spirit of its romantic dreariness in scaffolding subjects and street vistas, and these certainly approach a step or two nearer to the proper point of view. But, on the whole, London is as yet un painted.

For the fact is that sketching in London is hemmed around with deterrents and difficulties. Where life and commerce teems, the constable is inexorable, and that functionary is instructed to regard a standing figure as an obstruction, to say nothing of an easel or even a box and stool. Window space is hard to command at any price, and if it were not, the preliminaries necessary are quite enough to damp the enthusiasm of a man who likes to do his work upon the immediate impulse. An omnibus seat is almost the only good point

of vantage open to an observer, and from such a transient standpoint his work, when it has been ultimately accomplished, is performed not more than an impression in the strictest sense of the word. A few minutes watching is all that is available, and the artist must in that time store his memory with a thousand differing facts if he is to turn out a masterpiece. Only consummate power with a lifelong habit and knowledge can hope to succeed under such conditions.

Due to that fact, without doubt, is the slight feeling of disappointment that follows an examination of most of the works that have London views as subject. Few seem to show sufficient subtlety in observation either of London air or London light. There is a crudeness and want of *nuance* never found in actual London views, which are generally broad, delicate, and full of gradation. In pictures where a quiet and all but permanent position for work has been possible, as in river scenes, these drawbacks should be non-existent. Further, there is no excuse in such cases, either for ill-digested observation, or for wanton carelessness in the putting down of the forms of such well-known landmarks as St. Paul's or the Houses of Parliament, buildings which were lamentably treated in a recent show of London pictures at the New Dudley Gallery.

The photographer scores in the matter of form, however matter-of-fact his picture may be as regards subtleties of tone (I am, of course, speaking of the works of artistic amateurs), he does not produce a St. Paul's that at a first glance might be mistaken for the New Old Bailey or for the church of the Salute at Venice. It is generally taken for granted that a painter in the heat of getting an impression is justified in ignoring the claims of form when they divert his attention from the seizure of more elusive things. But there are one or two points to be considered in a matter like the present. The first is whether a hit-or-miss regard of form is not sometimes an indulgence and nothing more, or an adventitious way of putting a false value upon colour and tone. A good draughtsman does not use up any appreciable amount of energy in putting down his forms calmly and with due regard to proportion. In the hastiest sketches of Sargent, for instance, his drawing is perfect, and that is one reason why his impressions are so convincing. Another point is, whether, in such an avowed object as the painting of London as London, not as mere exercise in paint, the artist is not under some obligation to represent its landmarks with something more of familiar truth, as Guardi and the Canaletti and the Dutchmen represented their own cities. Mere detail is another matter, and is better suggested than made out; but it ought to be there, in suggestion. The masses and forms of the great London buildings being, for the most part, fine in themselves, a wanton and regrettable sacrifice of beauty is involved when such faults occur as the painting of the dome of St. Paul's here egg-shaped, there globular, at another place like a hard felt hat, and again, toppling into the street below, or with exaggerated orders and mouldings in one place and with none at all to speak of in another.

It is only fair to say in this connection, that of all the pictures in recent exhibitions, the London impressions now on view at the Fine Art Society's rooms, painted in water-colours by Mr. W. Walcot, combine most successfully a perfect impression and adequate drawing. That is to say, that the buildings, vehicles, etc., are put down with a deftness and sureness of touch that seems in no way to rob from the true effect of colour and tone. Tone, perhaps, is more Mr. Walcot's *forte* than colour; but his sense of proportion is always respected. He never allows himself to play fast and loose with these demands of realism; in fact, it is easy to see in one or two of the charming renderings of Westminster Abbey that he has ruled the lines that were to guide him in depicting certain architectural features.

The result is a sense of solidity in his buildings which the generality of artists do not achieve. Certainly the majority of the New Dudley Gallery drawings did not achieve it. There is just a suggestion that photographs have been of some service to Mr. Walcot in working out his drawings from rough colour notes. It may be. But no fault should be found with such a resource if the final result gains so distinctly, and loses nothing that belongs to a true impression.

Readers may remember a reference to the London pictures of Mr. Talmage in these columns recently. They are also conscientious in a different way, though scarcely so much an attempt to render the romance and glamour of London as an attempt to reproduce with fidelity certain phenomena of London lighting. Much more poetic are the works of Mr. A. Carruthers Gould, R.B.A., who respects the proportions of our buildings, and gives fine colour schemes into the bargain.

His view of Cannon Street Station seen from an arch or bridge, is a beautiful nocturne. The tone of the sky and the colours of the lights of signals and trains, and the play of all upon smoke and steam, is well observed, and makes a beautiful subject. A similar "Nocturne," where electric lights upon the water shine, perhaps, a thought too brilliantly for pictorial purposes, if not for truth, together with another work of barges in snow, are perhaps the best of his series, which are all characterised by earnestness of purpose and poetic vision. Mr. Tatton Winter, R.B.A., paints vigorous water-colours in a direct method. His "London Bridge," with its slight screen of vaporous air and its wheeling sea gulls, is an excellent work, and his view of the Serpentine is broad and fine in effect.

Mr. Edgar Down's idea of London is largely confined to its horses, which are smartly enough painted; but are scarcely London. Half a dozen of his pictures have excellent effects, nevertheless, and his "Night effect," a "road up" scene, only too well known to Londoners, is new and arresting, if not beautiful. Most of the skies of Mr. Owen Bowen, A.R.C.A., are heavy with storm cloud. He brings his buildings out light against them in rather a mannered way.

London as a place beautiful, is appealing more and more to its artistic inhabitants, and photographers are not even upon the fringe of the subject yet. They could not have better guidance and suggestion than that afforded by the examples of the small group of artists who are attracted by the unique charm lying in the vaporous breadth and tender colouring of the great metropolis; the city of certain characteristics which other cities do not share.

F. C. TILNEY.

## Patent News.

*Process patents—applications and specifications—are treated in 'Photo Mechanical Notes.'*

The following applications for patents were received between January 27 and February 1:—

**COPYING.**—No. 2,076. Improved mechanism for the production of photographic copies and the like. Jakob Röttgen and Julius Frey, 322, High Holborn, London.

**CAMERAS.**—No. 2,142. Improvements in stereoscopic cameras. Jules Richard, 53, Chancery Lane, London.

**COLOUR PHOTOGRAPHY.**—No. 2,213. Improvements in and relating to three-colour reticules for colour photography. Robert Krayn, 33, Cannon Street, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**ARC LAMPS.**—No. 19,014, 1907. The invention relates to electric lamps in which the light rays are concentrated by enclosing the source of light in a cylinder having a longitudinal slot, or opening, which may be closed to any desired degree by employing therewith an internal or external, cylindrical slide, or shutter, movable upon a concentric axis, and the invention consists of improvements in lamps of this class which are more especially intended to produce powerful illuminating effects in rooms where photographs are taken.

A cylinder is provided consisting of two portions forming shutters, which can be rotated so that one portion slides over the other (or each may be rotated), giving a maximum aperture of 180 deg. Within the cylinder is an arc light, the two electrodes of which are adjustably mounted one at each end of the cylinder.

The part 1 carrying the source of light is connected by a ball-and-socket joint 2 to the support consisting of a pillar 3 and a base 4. The source of light is an arc light, 5 and 6 being the electrodes to which electric current is supplied by means of the terminals 7 and 8. The electrodes 5 and 6 are clamped, by means of screws 9 and 10, between jaws 11 and 12. The light is produced within a cylinder 1 consisting of two portions, or shutters, 13 and 14, mounted so that they can be partly rotated; or either of the shutters, 13, 14, can be stationary and the other movable. By means of the shutters the illuminating effect can be regu-

lated as required, these shutters enabling an opening, or slit, of any desired width to be obtained for the passage of the light.

The arc light can be adjusted in any convenient way, such as by operating by hand a regulating spindle 15 provided with right and left hand screws, and shifting, when it is turned, the electrode holders 11 and 12, which are supported by a guiding rod 16 and provided with nuts to engage the said screws.

On a semi-circular piece, 17, of metal, or other suitable material,

Fig. 1.

Fig. 2.

a shade-holder can be mounted to carry a shade when it is desired to use the lamp as a table lamp. The ball-and-socket joint 2 enables the lamp proper to be adjusted to any required position.

J. Y. Johnson, for the Jupiter Elektrophotographische Gesellschaft, m.b.H., of 38, Schlossstrasse, Bockenheim, Frankfurt-on-Main.

**DAYLIGHT CHANGING AND DEVELOPING.**—No. 1,404, 1907. The first claim is "for the daylight production of photographic negatives from dry plates or cut films, the combination comprising a magazine camera and dark cell or plate-box fitted with means for cutting out each plate singly and after exposure discharging same into a similar plate-box in the lower part of the camera and a daylight developing appliance or box with which the box of exposed plates is made to engage in a light-tight manner and to discharge each plate singly into the interior." The twelve drawings of the apparatus and the descriptions thereof are necessary for a proper explanation of the apparatus. George Wishart, of High Bushmill, Cambuslang, and Frederick MacKenzie, 17, Douglas Street, Glasgow.

The following complete specification is open to public inspection before acceptance under the Patents Act, 1901:—

**OPYING.**—No. 1,615 Apparatus for reproducing at a distance graphic documents (photographs, blocks, drawings, etc.). Belin.

## New Trade Names.

**DEVOLVINE.**—No. 299,289. Photographic developers. Reitmeyer and Co., 63, Crutched Friars, London, E.C. January 4, 1908.

**DEVOLIN.**—No. 299,290. Photographic developers. Reitmeyer and Co., 63, Crutched Friars, London, E.C. January 4, 1908.

**ENCRO.**—No. 299,047. Postcards, photographs, and printed matter in the nature of booklets and circulars. Jack Benn and George Cronin trading as Benn and Cronin, 149, Great Titchfield Street, London, W. December 21, 1907.

**CLAPHAM CARLTON CAMERA CLUB.**—At a recent meeting of the Clapham Carlton Club it was decided to form a photographic section or those members interested in photography, thirty of whom have already been enrolled and the following officers elected:—President, Major F. Johnson; vice-president, Mr. James Arrow; committee, Messrs. H. E. Fuller (chairman), G. Bennison, A. E. Lomax, F. Van Neck, and B. Watson. The hon. secretary and treasurer is Mr. Herbert Tozer, to whom all communications should be addressed at Preston House, South Side, Clapham Common, S.W., and from whom all particulars as to membership, etc., may be obtained.

## Analecta.

### Diffusion Screen for Bromide Enlargements.

For some time past (writes Mr. R. Berry, in "The Photographic News") I have successfully used a coarser kind of muslin or butter cloth, which I attach to a light wooden picture frame of about 15 x 12 size. The muslin is first damped and afterwards tacked round the frame, a layer of stout drawing-paper equal to the width of the frame being superposed so as to increase the tacking surface. Of course, the cloth is pulled fairly taut during this operation, and when the screen is dry it will be found quite tightly stretched and without sag. The method of using the diffusing screen, from which, I think, the most pleasing results are to be obtained, is to interpose it about half-way between the lens of the enlarger and the bromide paper, keeping it in constant motion during the exposure. More diffusion can be obtained by using the screen nearer the paper, and vice-versa. The use of the screen will increase the exposure from one and a half to twice that which would be given without it. It should be remembered that when using bolting silk or any such screen, we may use it for two somewhat different purposes. First, to impart a dot-like half-tone block effect by using it close to the paper; second, to employ it to give a general softening effect by the method above described.

### A Delicate Test for Mercuric Chloride.

An interesting method of detecting minute traces of mercuric chloride (corrosive sublimate) (writes "Knowledge") has recently been devised by Herren Kof and Haechn. It is based upon the fact that if a sensitive photographic plate be placed film downwards at a distance of 5 to 10 millimetres from the surface of a dilute solution of the salt, the subsequent development of the plate is retarded. By placing a narrow strip of glass across the top of the beaker containing the solution, that portion of the photographic plate covered by it is protected from the radiation, and it is possible, after sufficient exposure in the dark-room to obtain subsequently an image of this protecting diaphragm upon the plate. This action of the mercuric chloride solution on the plate may be prevented by adding common salt in such proportions that a considerable amount remains undissolved, an inactive double compound apparently being formed. If now, however, a solution of tin chloride be introduced, dissociation and reduction of the mercury compound begins, and the photographic plate is again affected, but with this difference, that an image of a diaphragm between appears as a positive instead of as a negative on development. The reaction is obtained with solutions containing from 0.01 to 6 per cent. of mercuric chloride, but not with a 0.001 per cent. solution. In comparative experiments, in which a beaker containing a 2 per cent. solution was covered with moist absorbent paper, it was found that the mercury salt volatilised at the rate of 0.000000011 gramme per square centimetre of paper in thirty minutes (the time after which the first faint reaction could be observed on a photographic plate). These values were found by saturating similar pieces of paper with solutions of mercuric chloride of known strength, and comparing the stains given by these, on exposure to sulphuretted hydrogen, with those given under the same conditions by paper exposed at a distance of 5 to 10 millimetres above the test solution. If a drop of a 0.01 per cent. solution be placed in a cavity in an object glass and the film of a plate exposed to its action at the distance stated for 24 hours in the dark-room, the image of the drop will appear as a white spot upon the plate after development.

**GERMAN TARIFFS.**—It is announced that the duty on "lichtpaus" paper—that is, papers such as ferro-prussiate and others used for the copying of plans—is 10s. per 100 kilogrammes.

**THE SCOTTISH NATIONAL SALON**, which is being held this year in the Art Gallery, Aberdeen, will be opened at noon to-morrow, February 15, by the Very Reverend John Marshall Lang, C.V.O., Principal of the University of Aberdeen, and will remain open till the evening of March 7. A musical entertainment, a lantern exhibition or a lecture (illustrated by lantern views), has been arranged for each evening during the three weeks the Salon is to remain open. The exhibition will be open daily from 12 to 5.30 and 7 to 10, Saturdays 11 to 10, the special entertainments commencing each evening at 8 o'clock.

## New Apparatus, &c.

The Cuckoo House. Sold by Marion and Co., Ltd., Soho Square, London, W.

Messrs. Marion have just introduced this studio toy for the delectation of the infant mind. It consists of what is described as a "cuckoo house," though whether the edifice answers correctly to the description, our knowledge of the subject, we regret to say, is not

sufficient for us to speak authoritatively. At any rate it is enough to state that pressure upon a lever, which projects from the "basement" of the "cuckoo house," causes the bird to appear at its front door, and to announce its presence with a loud "cuckoo." Four shillings and sixpence will purchase this phenomenon and pay the carriage on it.

## New Materials, &c.

"Cubrome" Thiomolybdate Sepia Toner. Made by Edmund and Co., 3, Ezra Street, Columbia Road, London, E.

A new departure in the sepia toning of bromide and gaslight prints, frequently described as the sulphide process, is made in the issue of this preparation. Readers of Mr. H. E. Smith's communications in reference to the process will be familiar with the chemical fact upon which it is based, namely, the use of a solution of thiomolybdate in place of that of sodium sulphide. Apart from the comparative absence of any odour due to the sulphuretted hydrogen, the method has certain advantages claimed for it which in our experience of it have been quite borne out. As sent out by Messrs. Edmund, the preparation consists of a bleaching solution, which is diluted with an equal quantity of water for use, and of a toning liquid, 5 minims of which are added to two ounces of water. A bromide print of average intensity bleaches in something less than a minute, is washed for one to two minutes, and is then immersed in the toner for a full five minutes. A final washing of twenty minutes in running water completes the process. The proper length of time in the toner should be insisted on, as the full depth of brown colour is not obtained by shorter immersion. If, owing to prints being removed too soon, the tone is not sufficiently brown, the prints may be re-immersed in the bleacher for five minutes, washed and toned again, or they may be placed in a weak bath of ammonia, 3 per cent., for two or three minutes. Either treatment will improve the brownness of the tone. The first advantage which the process is seen to have is that it gives a slight—very slight—intensification to the print. Although its tendency in this respect is not enough to require a print of less intensity to start with, yet it has the effect of giving sparkle and brilliancy to the print owing to the fact that the lesser colouring power of the toned image is compensated for by the slight increase in the deposit. A comparison of a print toned by thiomolybdate and with sulphide will show the advantage of the former method in this respect.

Our own trials have been made with bromide prints, but in regard

to gaslight the makers claim that the thiomolybdate does not produce the yellowish shade of tone which is not uncommonly the result of sulphide toning. As regards the permanence of the result, the silver sulphide formed is certainly as permanent as that produced by the ordinary sulphide process. The proportion of molybdenum sulphide which enters into the composition of the image is at any rate no less permanent than silver sulphide. There certainly seems good chemical reason for the permanency of the toned prints, and the method is altogether one which will re-intensify the popularity of sepia-toned bromides.

A circular of instructions has been issued by Messrs. Edmund and gives the precise manipulation advised by them for their patented process. The solutions themselves, our results with which we have just described, are sold in packets, price one shilling, and will be obtainable immediately from Messrs. Edmund or from photographic dealers.

"Graysinn" Matt C.C. Paper. Sold by F. E. Jones and Co., 22, Gray's Inn Road, London, W.C.

From samples of this paper which we have had under trial it has been evident to us that amongst the products which Messrs. Jones supply specially for the purposes of the professional photographer, their collodion paper is one which can be commended. Collodion-chloride, on account of the rich appearance of the prints and the fine tones obtained on it by gold *plus* platinum toning, is so largely in favour that a professional has certainly to decide upon some brand or other of it unless his business caters for none but the cheapest, or, on the other hand, the highest type of sitter, who will have sepia, platinum, or carbon. For the great average, however, collodion-chloride provides a handsome and reasonably inexpensive print, all to the credit of which are the close imitations of its character by some of the makers of gaslight paper. As we have found it, the "Graysinn" paper tones readily and to a series of satisfactory colours. It is free from curling and cracking tendency when handled with ordinary precautions, and may thus be said to answer all the requirements demanded of a C.C. paper. It is made in the following four grades: "Smooth white, thin," "smooth cream, thin," "rough cream or white, thick," samples of which are obtainable on application to 22, Gray's Inn Road, W.C. Messrs. Jones have shown us a remarkably fine series of prints made by professional users of the papers, a selection of which could no doubt be examined by any professional photographer applying to them.

The "Glueless" Squeegee.—Made by the Thornton-Pickard Manufacturing Co., Ltd., Altrincham.

The name of Thornton-Pickard having long been the hallmark of efficiency in camera and shutter construction, it is satisfactory to find that the firm is not to restrict its energies to these branches of the photographic wood-working trade, but, as evidenced by its first introduction of a minor accessory, aims to supply the photographer with the smaller but equally essential tools. In the "Glueless"

squeegee the rubber blade is provided with the dumb-bell-shaped end seen on the right of the drawing, and is thus held in the specially grooved handle without glueing. The handle itself is of a specially convenient rounded form, and the rubber blade is screwed in it, so that in the case of a new rubber being required it can be inserted by simply removing a couple of screws and taking out the worn-out rubber. The squeegee is certainly a most workmanlike article for hard wear, and is obtainable in five sizes from 6 to 18 inches in length, prices from 2s. to 6s. each. New rubbers are obtainable at prices from 1s. to 3s. each.

LETO GREEN TONER.—In reference to our review last week of a green-toning preparation, the Leto Photo-Materials Company, 3, Rangoon Street, E.C., remind us that a pair of solutions for the same purpose is supplied by them with other Leto toners. We must admit that the fact escaped us when writing of the new preparation, but

we have since renewed our acquaintance with the active properties of the solution, which we can say allow of the rapid toning of bromide prints. The composition of the Leto toner evidently differs from that of the preparation which we have reviewed, and it will doubtless interest those desirous of obtaining a range of green tones to compare the results by the two solutions side by side.

### CATALOGUES AND TRADE NOTICES.

**TRESS SPECIALTIES.**—A new catalogue issued by the Tress Co., of 4, Rathbone Place, Oxford Street, London, W., is, like other publications of this firm, stocked with particulars and illustrations of novelties of essentially professional interest, all at most moderate prices. It contains, among other items, details as to a new studio gas portrait lamp, dry-mounting machine, panel repeater, and numerous accessories, frames and backgrounds. It is most emphatically a list which the professional photographer should have by him for reference.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, FEBRUARY 14.

Sutton Photographic Club. "Photographic Tiles and Platinotype on Linen." E. A. Salt.  
Lancaster Photographic Society. "A.P.' Prize Slides."

MONDAY, FEBRUARY 17.

Southampton Camera Club. Lecturette Competition.  
Lancaster Photographic Society. "Development of Autochrome Plates." R. W. Waring.  
Bradford Photographic Society. "Genre and Figure Studies." T. Lee Syms, F.R.P.S.  
Scarborough and District Photographic Society. Focus Prize Slides.  
Stafford Photographic Society. "Lantern Slide Making." W. Kirkham.  
Kidderminster and District Photographic Society. "P.O.P. Toning." W. Thompson.  
Harrow District Photographic and Scientific Society. "Platinotype." J. Richardson.  
Workington Photographic Society. "Tabloid" Photographic Chemicals.  
Catford and Forest Hill Photographic Society. Monthly Competition—Criticism.  
Dr. A. R. F. Evershed.  
Canterbury Camera Club. Rotary Carbograph Paper.

TUESDAY, FEBRUARY 18.

Royal Photographic Society. "London in the Eighteenth Century." A. H. Blake, M.A.  
Epsom and District Literary and Scientific Society. "After Treatment of the Negative."  
Hackney Photographic Society. Annual Dinner.  
Birmingham Photographic Society. "Amongst the Foothills of the Eastern Alps." J. Dudley Johnston.  
Working Camera Club. "Hford Lantern Plates." Algernon Brooker.  
Wimbleton and District Camera Club. "Flower and Fruit Photography." Edward Seymour.  
Sheffield Photographic Society. "The Theory and Practice of Time Development." W. F. Slater, F.R.P.S.  
Elaiogorie and District Photographic Association. Annual General Meeting.  
Maldstone and Institute Photographic Society. Rotary Carbograph Paper.

WEDNESDAY, FEBRUARY 19.

Borough Polytechnic Photographic Society. "Flower and Fruit Photography." E. Seymour.  
North Middlesex Photographic Society. "Bromide Printing and Toning." E. R. Mattocks.  
Central Technical College Photographic Society. "The Pinatype Process." A. Rogers.  
South Suburban Photographic Society. "Combination Printing and Printing." Ernest Human.  
Mill Camera Club. "Copying." W. Mansfield and W. Richardson.  
Woodford Photographic Society. "Rawlins Oil Pigment Process." J. J. Griffin & Sons.  
Leeds Camera Club. "Further Experiments in Bromide Toning." Fred. J. Webster.  
Bristol Photographic Club. "A Description of Hand Cameras and their Use." J. S. Guthrie.  
Croydon Camera Club. "Hints on Mounting Prints." E. A. Salt.  
Lancaster Photographic Society. Annual Supper.  
Margate Photographic Society. Rotary Carbograph Paper.

THURSDAY, FEBRUARY 20.

Bath Photographic Society. "Sutting the Printing Process to the Negative." S. R. Lewin.  
Handsworth Photographic Society. "Midland Federation Portfolio."  
Hull Photographic Society. "Theory and Practice of Time Development." W. F. Slater.  
L.C.C. School of Photo-Engraving and Lithography. "Lettering." A. E. R. Gill.  
Richmond Camera Club. Affiliation 1907 Prize Slides.  
London and Provincial Photographic Association. "A Photo Mechanical Process." Archer Clarke.  
Liverpool Amateur Photographic Association. "Magnesium Light Photography." F. J. Mortimer, F.R.P.S.  
Midlothian Photographic Association. "Ozobrome." Geo. Cleland. "One Man Show." E. L. Brown.  
Chelsea and District Photographic Society. Annual General Meeting.

Rugby Photographic Society. "Lantern Slide Making." B. B. Dickinson, M.A.  
Leek Photographic Society. "Tabloid" Photographic Chemicals.  
Dover Institute Photographic Society. Rotary Carbograph Paper.

### ROYAL PHOTOGRAPHIC SOCIETY.

THE annual general meeting was held on Tuesday last, the President, Mr. J. C. S. Mummery, in the chair.

The deaths were announced of Mr. F. Dunsterville and Mr. E. R. Cassells, Fellows of the Society.

The presentation of the Progress Medal (1908) was made to Mr. J. Sterry, upon whom has also been conferred by the Council the Honorary Fellowship of the Society.

In discussing the report of the Council Mr. H. Maclean suggested with regard to the "Journal" that the notices of new apparatus and materials were incomplete. He would discourage the continuance of such notices; it was best to do reviewing thoroughly or not at all.

In reference to the exhibition, Mr. Maclean put a resolution that the pictorial section committee each year should include two members who had not previously served. This was seconded, but was lost on being put to the meeting.

The President drew attention to the omission from the report that the thanks of the Society were due to Mr. E. O. Hoppe for his valuable aid in obtaining the foreign exhibits at the Society's exhibition.

Arising out of the Council's reference to the library, Mr. E. J. Wall thought that an effort should be made to arrange the books according to subject. The President stated that the intention was to appoint a small committee to deal with the library.

In reference to the Society's museum, the Rev. F. C. Lambert asked whether a catalogue could not be published. The longer such a duty was postponed the more difficult it became to discharge it. Mr. Oliver Dawson suggested that the catalogue should be illustrated; it should be, he thought, a scientific work. Dr. C. E. K. Mees put forward the suggestion that the museum might be added to by gifts from exhibitors in the technical section of the Society's annual exhibition.

Some discussion took place as to the formation by the Society of a national photographic portrait gallery. It was explained that such a collection would consist of photographic portraits, very carefully selected, of British celebrities.

In regard to the affiliation it was stated that 157 societies in the United Kingdom, and thirteen in the colonies, were now affiliated. The cost of the affiliation to the R. P. S. included certain office work, the use of rooms, a copy of the "Journal" to each society, and admission at half-price to the exhibition. It was stated that 4,796 half-price tickets, representing £120, were presented at the last exhibition. One speaker suggested that the Society was £120 out of pocket on this transaction, but another member, who appeared to voice the general opinion of the meeting, thought that the greater portion of these tickets were paid for by persons who otherwise would not have visited the exhibition.

Votes of thanks to the various officers of the Society and a special vote to the treasurer concluded the discussion of the report.

The following have been elected officers for the present year:—

President: Mr. J. C. S. Mummery; Vice-presidents: Sir W. de W. Abney, The Earl of Crawford, Sir Joseph W. Swan, Major-General J. Waterhouse; Treasurer: John Sterry; Council: T. Thorne Baker, A. W. W. Bartlett, Henry W. Bennett, Leslie E. Clift, Douglas English, T. E. Freshwater, John H. Gear, E. T. Holding, G. Lindsay Johnson, Rev. F. C. Lambert, Furley Lewis, Ernest Marriage, A. Marshall, F. Martin Duncan, C. E. K. Mees, F. J. Mortimer, C. Welborne Piper, E. Sanger-Shepherd, H. Snowden Ward, B. Gay Wilkinson.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—On Thursday, February 6, a large number of members and friends gathered at the house-warming social of the L. and P. at the Olde Napier Tavern, 25, High Holborn. Mr. T. E. Freshwater (in the chair), addressed words of welcome to all, saying that the Association had passed its twenty-fifth birthday, and that the officers had hopes of it living at least another twenty-five years. They had long been dissatisfied with the old meeting-room, where they had been stationed some thirteen to fourteen years, and he thought all would admit

that present quarters were more comfortable than the old one. An interesting musical programme followed.

**EDINBURGH PHOTOGRAPHIC SOCIETY.**—At a meeting on February 5 a lecture, entitled "With Motor and Camera in Normandy and Touraine," was given by Mr. John Warrack. In commenting on the beauty and charm of the old churches and cathedrals which are such an interesting feature of the neighbourhood of Rouen, Caen, and Blois, Mr. Warrack said that the spirit which, 700 years ago, led men to plan "those long-drawn aisles and fretted vaults," was now largely diverted into the more secular and unromantic channels of applied science and mechanics. Excellent lantern slides from Mr. Warrack's own negatives showed the photographic possibilities of Normandy and Touraine.

**CENTRAL TECHNICAL COLLEGE PHOTOGRAPHIC SOCIETY.**—"Gum-Bichromate" was the subject of a very interesting lecture given by Mr. D. R. Pimock on Wednesday, February 5. Following the lecture a demonstration of the process was given, when several excellent results were obtained. Further prints were handed round, illustrating amateur and professional work on "Page-Croft" pigment paper.

**SOUTHAMPTON CAMERA CLUB.**—Mr. A. E. Henley gave his lecture, entitled "Some Cathedrals I have visited," at the Philharmonic (small hall), on Monday evening last before a large audience.

## Commercial & Legal Intelligence.

**SEPIA BROMIDE IN THE COUNTY COURT.**—In the Birmingham County Court on February 7, an interpleader action to recover a formula relating to a secret photographic process was brought by the Page Croft Paper Company, the nominal defendant being W. Harold Kimpton, solicitor, of Birmingham, and the claimant John H. Gillard, photographic expert, of Watford. Mr. J. G. Hurst (instructed by Mr. W. H. Stoddard) appeared for the plaintiffs. The claimant did not appear, and the defendant stated that he had no objection to giving up the formula. Mr. Hurst explained that Mr. Gillard was the inventor of a secret process in connection with a brown sepia bromide paper for direct development without subsequent toning. He agreed with the plaintiffs to deposit the formula with Mr. Kimpton pending the formation of a company, and to continue his experiments at the plaintiffs' works. He had failed to complete his experiments and to comply with other terms of his agreement with the plaintiffs, and in consequence of the breach of agreement the plaintiffs were entitled to take possession of the formula. After hearing formal evidence, the Judge made an order for the formula to be handed over to the plaintiffs, and barred the claimant from making any claim against Mr. Kimpton in respect of it.

**PHOTOGRAPHER AND MINING SPECULATIONS.**—In the King's Bench Division on February 7, Mr. Justice Bray and a common jury concluded the hearing of the action in which Mr. Henry Bown, formerly a photographer in business in New Kent Road, S.E., claimed £1,000 from Mr. Thomas Isaac Grimes, accountant, of 32, Great St. Helens, which, he said, he advanced as a loan. The defendant, a director of the Nigel Main Reef, Ltd., denied liability or that the £1,000 was a loan, and said that the sum was placed at their joint account at plaintiff's bank for purposes in connection with the company. The jury found for the plaintiff, and his lordship gave judgment for the amount claimed, with costs.

**NORWICH BANKRUPTCY.**—The first meeting of the creditors of Percy John Swain, of 37, Earlham Road, Norwich, carrying on business under the style of John Percy, at 2a, Davey Place, Norwich, formerly also carrying on business at the same place, and at Oxford Place, Norwich, in partnership with Louis Smith, as Louis Smith and Co., photographer, was held at the offices of the Official Receiver at Norwich on Monday. Debtor's statement of affairs showed twenty-eight unsecured creditors for £243 12s. 9d., and one contingent liability to rank against the estate of £15. The deficiency is £164 11s. 1d. The causes of failure, as alleged by the debtor, are insufficient earnings at Hastings to meet expenses. The Official Receiver reported that the debtor started at White Rock, Hastings, as a photographer,

in 1902, with a capital of £25. The business was unsuccessful, and in January, 1906, all his effects were sold under a distress for rent and an execution, which left him with liabilities amounting to over £100. Between January 1906, and March, 1907, debtor has held situations in the photographic business at Hartlepool, Humstanton, and Boney, N.B.

The Official Receiver will wind up the estate under a summary order.

### NEW COMPANIES.

**DISSOLUTION OF PARTNERSHIP.**—The partnership between William Edward Hailstone and Thomas Knight, photographers, of High Street, Hadlow, Kent, has been dissolved by mutual consent.

**LEGAL NOTICES.**—Creditors of the Pictorial Postcard Company Ltd. (in liquidation), are requested to send their claims to E. H. Stringer, chartered accountant, of 110, Cannon Street, E.C., by February 9.

A receiving order has been made against Sidney Butt and Josiah Butt, photographers, of 35, Tabernacle Road, Skewen, Glamorgan.

A first and final dividend of 2s. 11d. in the £ is to be paid in the bankrupt estate of John Edward Reeves, photographer, of 48 and 50, Hermit Road, Canning Town. Payment will be made at Bankruptcy Buildings, Carey Street.

**WILLIAM TYLAR (ASTON).**—This company has just been registered with a capital of £5,000 in £1 shares (1,000 6 per cent. cumulative preference), to take over the business of a photographic apparatus manufacturer carried on by W. Tylar at 41, High Street, Aston, Birmingham. The subscribers are: W. Tylar, Mrs. C. Starkey, B. Starkey, A. I. Knutton, J. T. E. Roberts, Mrs. K. Fletcher and Mrs. L. Phillips.

## Correspondence.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

### PHOTOGRAPHERS AS PROFESSIONAL MEN.

To the Editors.

Gentlemen,—As one of the midget men, those common people who have no purpose in living, and yet, seemingly, have no great inclination to die, may I make a few remarks on this question of "Photographers as professional men"?

I have been interested and not a little amused by the correspondence, but my amusement reached its height when I read Mr. Goodyer's letter last Friday.

Now, I have no doubt that Mr. Goodyer is an artist with a large amount of "soul" (as he terms it) in his work, and has accordingly "no cause to complain of his social position," but I want to ask is there not a good deal of humbug and snobbishness in this idea of his of weeding out what he is pleased to call "the unfit"?

Now, by Providence, I am a photographer, as he and your other correspondents are. They may take cabinets, put "soul" into their work, gain the glory, and if that's the main reason for them keeping open their shops (I beg pardon! I mean "studios")—no brass plate, please!—verily, they have their reward.

But I am an unfortunate individual. I open my shop for a living—for bread and butter. I take midgets, sticky-backs, anything that a camera will take. I may not raise the standard of photography—I don't want to. I open my shop for something to eat, and I cannot eat glory, but I can eat bread and butter, and, verily, I have my reward!

Now, why should Mr. Goodyer want to weed out what he so superciliously calls the unfit. If, as he says, "the work of an artist will always meet with its reward"—i.e., glory and social status—why worry about weeding out poor me? Why waste his "soul" on that? No, he knows better. He knows that the midget man is making money, retiring early, and putting his soul into his motor car, while

and his confrères are still at it plenty of merit, plenty of social position, but precious little of the very useful £ s. d.

Well, I repeat myself—verily, they have their reward, and they are welcome to it says

ONE OF THE UNFIT.

February 9, 1908.

To the Editors.

Gentlemen,—With regard to Mr. Goodyer's contention in last week's "B.J.," that the subject of the status of photographers is being taken too seriously, I would point out that one's status is intimately connected with the amount of business done. Take the case of a doctor. If his social standing is improved his practice improves also. One can easily see that a doctor who is, socially speaking, in a good position, has a better chance of succeeding than one who is "not known," or not recognised by the well-to-do people. It is much the same with a photographer. If he has the social tact to be able to meet his clientele on an equal footing, socially, he is almost certain to benefit by it, for he will be introduced to their friends, who will possibly become his clients. This is more noticeable in smaller towns where the photographers are perhaps not more than four in number. All four may be capable of turning out work of excellent quality, but the one who is greatest, socially speaking, will do the best business.

Personally, I think photographers would benefit greatly if they could, by examination, attain a degree. Most other professions have this advantage, an advantage which gives them a certain amount of social standing. It would also touch very closely the question of "fit and unfit."—I am, yours faithfully,

ALFRED WRATE.

The Avenue Studio, Lumley Avenue, Skegness,  
February 8, 1908.

To the Editors.

Gentlemen,—Many of the readers of your valuable journal will no doubt have been interested to read the letters and articles of your various correspondents relating to the status of professional photography and how to raise it.

I think the reason for the present state of affairs lies in the fact that the vast majority of photographers, contrary to the general opinion, are not an intellectual class, from whence come all the petty jealousies and narrow-mindedness one so often sees exhibited by photographers. Look at all the other trades and professions; it does not matter how low they may be from a social standpoint, yet they nearly all have their societies or trade unions, but the better-class photographers have not sufficient intelligence or comradeship to organise themselves properly.

However, the question now is, how to raise the status of professional photography, and having had experience of practical professional photography in several countries, I have come to the conclusion that the only way to improve the state of affairs is the following:—

In the first place, all the professional photographers must be organised—employers and employees. Secondly, no photographer should be allowed to take an apprentice. The apprenticeship system should be abolished, and instead everybody desirous of becoming a professional photographer should, so to say, be obliged to take his degree in photography, like a doctor or lawyer, which could be arranged at several universities—for instance, at Edinburgh, Birmingham, or London, where special courses could be given in optics, chemistry, book-keeping, art and practical lessons in all branches of photography; and, say, after a three years' training in one of these universities, or a special university for photographers, and having been duly qualified by exam., then, and only then, should the would-be photographer be granted a licence to carry on business as a professional photographer; and also, before being admitted to this training, the novice must have passed a certain standard in other schools. In this way, in about twenty years' time the photographer would reach the same sort of position as the doctors and lawyers, there would be much less competition, and the standard of work generally would be on a higher level. Also, it would not harm the faddists or amateurs; they would still be able to make their art studies to their hearts' content, only they would not be able to sell them, not having the necessary licence. When a student of photo-

graphy shall have received his diploma he would find at once well-paid employment. Owing to the fact that it would cost nearly as much to become a photographer as a lawyer or any other profession, the class would consequently be greatly improved socially. Just think, in twenty or thirty years' time, if this system was adopted, there would not be canvassing, or free sittings, etc., it would be looked upon as being too unprofessional, and photographers would be looked up to as a highly respectable class.

In regard to assistants they should be allowed to frequent evening schools in order to obtain the diploma, practical knowledge being allowed to count to a certain extent in place of theory.

Press photographers should be classed apart, but should be obliged to have a licence in order to sell their work.

I think you will see that the general idea of this is to prevent the two or three weeks' old amateur setting up as a photographer, and so causing unnecessary competition and bringing discredit on professionals generally.

In conclusion, please excuse me for taking up your valuable time, but I should be only too pleased if I could do something to help the profession towards a higher level, because sometimes I feel ashamed to say I am a photographer. One is always looked upon with just a little suspicion. I suppose people think they are going to be asked to come and have a free sitting, with a high-class finish enlargement thrown in, and as in this world nobody ever gives something for nothing, naturally the suspicion.—I remain, yours truly,

12, Via Dante, Milan, Italy,

ALBERT E. ELSY.

February 5, 1908.

[We are afraid our last correspondent is altogether too optimistic. If he makes a list of the professions which can be practised only by those with diplomas, he will find them very few indeed. It is not likely that powers will be obtainable to secure such protection for professions which do not involve danger to life or limb, and even dentists practise unhindered as "teeth institutes," unpossessed of a qualifying diploma. We regard the examination qualification as totally impracticable in the case of professional photography, and we regard the correspondence on this subject as confirming our own contention that the most advisable position for a photographer to aspire to is that of a maker and seller of portraits. of a craftsman ready to work according to a tariff of prices. We should like to hear of forcible arguments to move us from this opinion, but we cannot discover that they have been put forward so far in the present correspondence.—Eds., "B.J."]

## PINHOLE APERTURE NUMBERS.

To the Editors.

Gentlemen,—In the issue of December 20 I note a letter from Mr. Alfred Watkins in reference to priority or credit for the system of calculating pinhole exposures, published by me in "Camera Craft" in 1902, and later explained fully in my monograph on pinhole photography, No. 70 of the "Photo-Miniature" Series. I have noted from time to time discussion in the photographic press concerning claims Mr. Watkins was alleged to have made, but took no heed of them, believing that all disputes concerning priority are profitless and vexatious, and I would not have written this letter were it not to correct errors, manifest or implied, in that of Mr. Watkins. Mr. Watkins writes: "The fact is that it is a modification, and a very happy one, of a system originated by me. I devised the plan to name the pinhole aperture as if it were sixty times the real area, so that a calculation made in seconds will be correct if given in minutes, and Dr. Power adopted this plan."

These words seem to imply that I got the basis of my system from the writing of Mr. Watkins. The fact is, when I published my formula I had never heard of Mr. Watkins in connection with pinhole work, nor have I ever read a line that he has written on the subject. Furthermore, I do not consider that the relation of seconds to minutes is the important part of my formula. When I took up the problem of finding a quick and simple method of determining a pinhole exposure I found nothing in the field but complicated tables or formulae that called for the use of paper and pencil. Pinhole photography to be useful must allow of long or short extension of bellows (according to desired size of object or angle of view), and the use of several sizes of holes (which determine the quality of definition). No formula which does not allow for these is satisfactory.

When I standardised and named the holes by numbers, that, these multiplied by the camera extension in inches, gave the *f*/ value as a quotient, I produced a formula that a tyro could use under any circumstances. That the quotient requires multiplying by sixty is a minor detail, on which I laid no stress. It is for this simple method of obtaining the exposure under all conditions of extension and pinhole size for which I believe myself entitled to credit. That is my claim, and I have not seen as yet anything to invalidate it. I stated that Mr. Watkins' letter contained an error of fact. I refer to his statement that my No. 4 pinhole is 1/38 of an inch in diameter. It is about 1/75 of an inch, being 0.38 of a millimetre.

In conclusion, let me reiterate my lack of interest in all priority fights—they are of no value to science—and whether I or Mr. Watkins first solved this exposure problem is immaterial so long as it is solved; but this much is certain, if we both solved it, we did so independently. The historian will take care of us both—in the usual manner.—Yours,

H. D'ARCY POWER.

San Francisco, California.

## PHOTOGRAPHIC MATTERS IN CAIRO AND TURKEY.

To the Editors.

Gentlemen,—In "The British Journal of Photography" the week before last there appeared items of news about trade in Cairo and the "B.J." in Asia Minor. Both were particularly brief, and it may therefore be of interest if I enlarge upon these.

First of all, let me deal with Cairo. A "B.J." correspondent wanted to know how the photographic trade stood in that Egyptian town, and whether it would not be well to commence business out there. As a one-time inhabitant of the place, let me say at once that there is no room for any more photographic dealers there. What few there are do, I have every reason to believe, a passably good trade, but a new beginner, and a Britisher in the bargain, would meet with many rebuffs, which I need not take up space to refer to here.

That there is an enormous amount of photography done nowadays in that picturesque land I will not deny, but it must be remembered that the majority is done by tourists who, as a rule, arrive, fully equipped with cameras and spools of film. Plates are not used to the extent one would think, and some boxes I saw in a window there looked, judging from the jaundiced label, as if they had been there in the days of Pharaoh. It is, however, film spools that have the largest sale among visitors, and, although these keep fairly well, one cannot be surprised at some going wrong now and then in such a climate. I thought of commencing a dealer's business out there, but after making many inquiries decided not to do so, as I preferred to lose my money—if it was to be lost—here in England.

If anyone really wants to start business in the Near East that way I should recommend Jerusalem. In this city there is not—or was not, a short time ago—a really up-to-date dealer. Plates, etc., were sold by a professional, who did not forget to charge. I was asked 7s. 6d. for a box of half-plates, and paid it. Jerusalem is so full of subjects for the camera that, however well a visitor arrives supplied with plates or films, he is almost sure to run short, and as the visitors, as a rule, have money to spend they do not mind paying a good price for what they want rather than leave the country without exposures.

The second item in the issue of the "B.J." referred to was to the effect that an advertiser secured business from that part of the world. I can assure advertisers that they would get plenty business from announcements in the "B.J." if the Customs authorities were more sane and gentlemanly in manners. During my residence in the East I frequently heard the "B.J." referred to, and myself saw it in many places, amongst them being Constantinople, Jerusalem, Athens, Beyrout, and Nazareth. An English-speaking Arab photographer at the latter place has quite a photographic library, and is as up-to-date as the laws of his country permit him to be. Probably he is now awaiting the result of the R.P.S. election. In Constantinople I know of two photographers who make their own plates and prepare their own paper, but those of the better class, I am glad to say, are—in spite of the Sultan and his dislike for photography—using British plates and papers.

The mention of papers reminds me of an incident. I saw in the

window of a photographic dealer at Beyrout a show-card, advertising a certain British printing-out paper; the card had a specimen print upon it. As it hung in the full glare of an Eastern sun I suggested to the man in charge that it would be better for his business if he hung the print in the shade. "Have no fear," said he, "that show-card has been hanging there for two years." The print was as bright and as good as when it left the factory, an excellent testimony to the quality of British goods.

I don't suppose the Editor of the "B.J." has any instances of "Journal" being seized by the Turkish postal authorities. If he has not, he can take it from me that scientific and technical papers are often stopped. If there is something in them the Turkish officers whose work it is to look them over, does not understand, the matter is blacked out, or, more often than not, the paper confiscated and destroyed. There is an old story of a certain scientific book being stopped there because it contained the chemical symbol for water (H<sub>2</sub>O), which the wideawake Turkish censor interpreted as follows:—"Hamid the Second is O—a cypher—a nobody." Such being the case, one dreads to think what effect an article, say, by Dr. Mees would have upon him.

MINARDI EFFENDI.

## GLAZING P.O.P.

To the Editors.

Gentlemen,—Simplicity, speed, and accuracy is the desideratum of all who have much glazing of prints to do, and I would recommend to workers the following treatment, which I have never found to fail.

Prepare your glasses (I use old 12 x 10 plates) by freely cleaning with petrol and lightly polishing with a soft rag. After prints have been immersed in alum bath, wash for a few minutes, then lay off glasses, pass over blotting paper a roller squeegee, and the whole process is complete. Points:—

Never dry quickly.

Dry in warm room.

When using glasses for the first time use plenty of petrol.

If glazed at night the prints are fit to strip next morning, without delay.

French chalk is objectionable in several ways, and cannot be compared with petrol for speed and efficiency.

I glaze thousands, and rarely have a failure. Glass should always be placed on end, not flat.—Yours,

A. G.

35, Southgate Street, Winchester, February 8, 1908.

## A SIMPLIFIED SYSTEM OF DEVELOPING AUTOCHROMES.

To the Editors.

Gentlemen,—I have for some time past been using the Lumière Autochrome plates and making experiments with a view to simplifying the process of developing them, being by nature somewhat lazy. Perhaps some of the conclusions I have arrived at may be of interest to your readers, and I am therefore sending you for inspection three Autochromes—not perhaps the best I could select, but sufficiently good to show that the treatment I am about to describe is not entirely a failure. The best of the three was only treated with two solutions, and was finished and dried in ten minutes. I consider that it is better than it would have been had I followed the instructions for the use of the plates. Now to secure a good Autochrome it is necessary first to abstract from the film the salts acted upon by the light, and afterwards to render as opaque as possible the remaining salts. The developer recommended by Messrs Lumière is a frightful nuisance owing to its rapid oxidation, its staining qualities, the odour of the ammonia, and the use of alcohol, which tends to frilling. I therefore use Rodinal, rather strong (about 1 in 10) in order to lessen the time of immersion. The strength of the Rodinal, the amount of bromide (if any), and the time of immersion, may easily be found. Personally, I look at the plate by weak red light after it has become thoroughly wetted, and thus lost some of its sensitiveness, and develop until any white part of the object photographed shows quite black. The C solution is then applied, and reversal takes place, after which I again develop in the Rodinal developer, and the Autochrome only then requires two minutes rinsing and drying rapidly. The Rodinal should for the second

ment be used very strong indeed, for preference, as it then gives a blacker image. There is not the slightest need for intensification, which only increases the brilliancy of the colours at the expense of the transparency, and generally makes a mess of the prints in the majority of cases. The enclosed plate, representing a match box, etc., was treated exactly as I have described. One representing two glasses with the light coming directly through them was afterwards intensified very slightly, and the other developed in the pyro-ammonia, re-developed with Rodinal, and afterwards intensified considerably. The total cost of the chemicals necessary to work Autochromes in the way I have indicated is very indeed. Only two bottles are necessary. There is no staining of fingers, no nasty smell, the fixing, clearing, oxidising, etc., are rendered unnecessary, the time is reduced, and personally I obtain better results. Rodinal is a grand developer, when no fixing is used. It gives an image intensely black when used very concentrated, keeps well, is ready at a moment's notice, and I advise Autochrome workers to give it a trial, at all events for the re-development.—Yours, etc.,

WILLIAM E. CLIFTON.

Peter's Chambers, Nottingham, February 5, 1908.

Regarding the specimens sent by our correspondent, that of the box and the three glasses are a good deal beyond what one can aim at as the correct density. If this density is usually obtained by the method there is no need for intensification, but we can see whether there is the same control in adjusting the density by our correspondent's method which one has when using the acid-silver intensification.—Eds. "B.J."]

WILLIAM TYLAR, LTD.

To the Editors.

Gentlemen,—You will notice I have formed my business into a limited company. I would like through you to tell your readers that as managing director of the same, I shall extend still to their business that personal supervision that has had such good results in the past. Also that the professional section will have placed before them many novelties designed for their especial benefit. One of my objects—in fact, the main object—is to get even better results from my employees, many of whom will have a personal interest in the well-being of the company.—Yours truly,

W. TYLAR.

SEPIA PLATINUM PAPERS.

To the Editors.

Gentlemen,—I ask your usual courtesy in presenting to the photographic fraternity the danger lurking in some of the papers sold, by name at least, as sepia platinum papers, mostly of the cold development type.

I have in my possession several prints on the same, and have dozens of others that are in various stages of fading after a short period, much shorter than some of the bad cases of fading of silver prints. Now these are not platinum papers, at least they contain an appreciable amount of that metal, for a pure platinum print does not fade under hardly any circumstances; it may turn yellow or brown, sometimes from insufficient fixing.

Those who sell such prints to their patrons as permanent platinum prints commit an unconscious fraud and injure their own business, as much as that of the profession.

The absolute permanence of platinum prints, as well as their artistic quality, has done more to advance the profession in late years than any one cause, enabling photographers to obtain high prices for their supposedly permanent prints. I have only found this with cold development sepia papers. The only sepia paper sold for platinum development stood the tests I gave was the Willis and Clement's paper, made by the Platinotype Company.

The test for a platinum paper is very simple. A solution of cyanide of potassium of 5 to 10 per cent. will quickly bleach out the old development sepia papers that are not largely composed of platinum, but will have no effect on real platinum papers. The photographic dealers of most influence in this country are so much under the influence of trusts that they will not publish such facts as these.—Very truly,

D. BACHRACH.

London, February 1, 1908.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

J. Caddick, 166, Penn Road, Wolverhampton. Two Photographs of "Lord George Sanger outside the Circus Ring at the Olympic Fun City, Kensington."  
W. Findlay, 110, Leadside Road, Aberdeen. Photograph entitled, "A Silvery Path to the Silver City."

LENS QUERY.—Would you please state a fair price for a half-plate applanan lens (f/8)? This lens is fitted with iris diaphragm. There is also offered me a half-plate. They are both in good condition. FILLINGHAM.

It is impossible for us to express an opinion on the merits of lenses we have not seen or tested, particularly as we have never heard either of the names mentioned as makers of lenses. The best way for you to estimate their worth to you is to test them by taking a negative with each and see how they answer your requirements. The actual market value of the instruments is probably not more than a few shillings each.

RECOVERY OF DEBT.—I should be much obliged if you could inform me: (1) If I can claim the price of photographs taken but not delivered. A gentleman called on me and asked if I could take a wedding group of his son and party and asked the price. I showed him some specimens, and he said that he would have 1-1 plates at 15s. per dozen, or for less than a dozen 1s. 6d. each. Now, I have made a dozen, but I cannot get them to call for them. Can I claim the money? (2) Am I charging too much?—T. C. F. (North Wales).

(1) You should send the photographs to the customer's house together with the account. If it is not paid you must sue in the county court, when you will recover, providing the pictures you have taken are equal to the specimens you submitted to the customer in obtaining the order. It is possible that they are not satisfactory, and that is why they are not called for. (2) No. If your work is really good the charge is too little.

SITUATION IN FRANCE.—(1) Is it possible for a young Englishman (with slight knowledge of French) to secure a position in France or Belgium as operator, retoucher, miniature painter, etc.? (2) If so, through what medium would he be best able to obtain that situation? Also (3) what would be the average wage at a good class studio for assistant operator, retoucher, and finisher?—ASTICOT.

(1) English assistants are to be found in Continental studios. (2) "Photo-Revue," 112, Rue d'Assas, Paris. (3) It varies as much as it does here.

F. H.—So far as we know no gravity number is taken as a test of bisulphite lye. Obviously it would be of little value, since any sulphate present instead of sulphite would be reckoned as the latter. Perhaps the Lumière Co., Great Russell Street, W.C., who issue the solution, may be able to help you.

BICROMATE SENSITIZING.—Will you be kind enough to inform me if it is possible to treat an ordinary dry plate so that the silver may be removed from it in order that it can be sensitized in a

bichromate of potash solution, and used for the simplified collotype process such as the Sinop and others?—A. R.

The silver can be removed in hypo solution, the latter washed out and the plate then used for the purpose described.

JOHN MCGARITY (New York).—Joly-MacDonough screens are not now obtainable commercially. As regards the other process, you can get into communication by addressing c/o of the American Express Co., Waterloo Place, London, W.

A. M. NICOLSON.—You had better obtain a handbook on photo-micrography, such as that by F. Martin-Duncan, published by the "Amateur Photographer," 52, Long Acre, W.C.

H. W. C.—The gentleman is a Fellow of the Royal Photographic Society, and therefore a letter addressed to him at the Society's house, 66, Russell Square, W.C., will probably reach him.

VELETA.—The letters denote Hefner (lamp)-metre-seconds—i.e., the HMS is the exposure of one Hefner lamp for one second at one metre distant.

P. B. L.—Camera and lens are excellent for the purpose. The double extension is a great advantage for your flower photography, otherwise we should suggest the Sybil camera of Newman and Guardia as even more portable.

SNAPSHOT CAMERA.—Will you kindly inform me if it is possible to buy the "snapshot camera for the use of artists" described by Mr. Nelson K. Cherrill in your issue for June 28, 1907? If so, where can I obtain the instrument?—D. THEODORE TIMINS, Bordighera, Italy.

There is nothing of the kind on the market. The nearest approach is the Hales camera of the Hales Camera Co, Ridgewood, N.J., U.S.A.

LIVERPOOL.—(1) The blocking-out of the machinery is done with a fine brush charged with Indian ink, or with a draughtsman's steel pen. (2) Messrs. Dawbarn and Ward, 6, Farringdon Avenue, could possibly supply you.

E. HIGGS.—We are unable to suggest any cause beyond that mentioned in our first reply. We have tried the samples of paper you sent us with perfect success, and without any trace of spots. Faulty manipulation is no doubt the reason of your failure.

VARIOUS.—(1) Can you enlighten me as to the best filter to use to get a violet plate for colour printing—from a water-colour drawing or sketch? (2) Can you inform me of an invisible writing fluid that will show visible when exposed to light for two or three minutes?—DASH.

(1) If you mean a filter for the blue printer (red-sensation negative), a suitable dye is Biebrich scarlet, used with a Lumière C plate, or you can use a mixture of Fast red (2 parts) and tartrazin (1 part). (2) We should think the sepia sensitiser, as given in the "Almanac," page 833, would answer the purpose. It is slightly coloured, but if applied to a cream paper would be invisible. It will not, of course, fade after once being exposed.

P. W.—For the limited sum you propose to spend we do not see that you can do anything different from what is shown in the sketch. But you must bear in mind that your sitters will be illumined by a direct front light, which the small amount of side light will not materially influence. It would be preferable to have what glass there is at the north side. The corrugated roof would not give uneven lighting. The best way of utilising the erection will be to place the background diagonally at the south side, and have a curtain coming nearly to the ground from the roof at that side, which can be drawn so as to subdue some of the direct front light.

J. D. W.-P.—We presume the Hudson referred to is the late Mr. Hudson, of Ventnor. The business, we believe, is still being carried on under the title of Hudson and Son. Frith, photographic publisher, Reigate, is also dead.

ENQUIRER.—We would refer you to the reflex or B pattern of Newman and Guardia, Shaftesbury Avenue, W.

BOXING DAY.—1. We think your employer can insist that the notice is given on the day your wages are paid. 2. Certainly you can-

not. You must agree with your employer as to this. If you left without proper notice you cannot claim wages.

W. G. (Worthing).—Most certainly he cannot. There is no cleavage point among the legal matters of photography.

F. H. W. and others.—In our next.

C. HAWKINS.—They are very good, and the profile portrait may certainly be by daylight.

CHROMO.—Turpentine is usually used for thinning the balsam. We fear it will not be easy to cement a loose gelatine film. It is more usual to coat glass with a coloured gelatine solution and to cement a cover glass. This is done by pouring the balsam on the filter (warmed on an iron plate), gently superimposing the cover glass and allowing the latter by its own weight to press out the balsam.

NERNST PROJECTOR LAMP.—Messrs. Houghtons Limited have been appointed sole wholesale agents for the A. E. G. Nernst lamp, already reviewed in our columns. Messrs. Houghtons have the lamp got at 88-89, High Holborn, and they supply spare filaments and resistances at prices stated on a circular which is obtainable from them.

LONGRIDGE CAMERA CLUB.—Photographic interest has recently been awakened at Longridge, near Preston, with the result that a camera club has been formed for that district, of which we shall hope to give fuller particulars shortly. The first president and secretary are the Rev. R. W. Berry and Mr. J. Robinson respectively.

EDITORIAL CHANGE.—Dr. R. Neuhauss being about to start the Antipodes, Dr. Hans Knapp has consented to assume editorial superintendence of "Photographische Rundschau."

THE ENGLISH PLAY SOCIETY, of which Mr. Lyddell Sawyer, the well-known photographer, is chairman and hon. manager, have published a book of rules, in which the aims and objects of the society, together with the terms of membership and the advantages accruing therefrom, are fully set forth. A copy of the book may be obtained on application to Mr. Sawyer, at 153, Maida Vale, London, W.

THE DEATH took place at Blair Athol last week, of Mr. P. Cameron, for the last thirty-five years photographer at Pitlochry.

"VELOX" COMPETITIONS.—The awards in the December competition are as follows:—First prize (£2 2s.), J. P. Ettridge, Goldhawk Road, W. Second prize (£1 1s.), J. Smith, North Shields. Consolation prizes of 5s., W. Howard, Ilford; Mrs. Pearson, Keswick; R. Thurn, Helensburgh; Edgar Law, Croydon, Cambs; H. Barrie, Glasgow; Richard Miles, Hammersmith, W.; Alex. L. Bell, Hawick; Mrs. Percy Unsworth, Grange-over-Sands; H. A. Vokes, Scholings, Southampton; John S. Slack, Dewsbury; Edward D. S. Morton, Stirling; Miss V. Coates, Cheltenham. This competition completes the present series.

STREATHAM PHOTOGRAPHIC SOCIETY.—The second annual exhibition will be held on February 27, 28, and 29. Admission is free catalogue, to be obtained of F. E. Huson, 56, Salford Road, Streatham Hill, on receipt of stamp to defray postage.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

**Sulphide Toning.**—Mr. Welborne Piper contributes a valuable article describing the new facilities provided by the sulphide constituents, thioisannate and thiomolybdate. (P. 135.)

**Sulphide Toning.**—Mr. H. T. Munkman finds that the important results in controlling the shade of sepia-toned prints are exposure and development. (P. 139.) We point out that in his experiments bleaching agents, such as acid-bichromate, which contribute to the faded image, are not included. Such bleachers appreciably affect the final colour. (P. 133.)

**Sulphide Toning.**—Methods of reducing sulphide-toned prints is the subject of a paper read before the South Suburban last week by Mr. H. E. Smith. (P. 137.)

Mr. R. E. Blake Smith contributes a paper on the theory of tint-out paper, which raises a number of new points and contains new practical information on the production of red tones. (P. 140.)

**Profitable Carbon Printing.**—We conclude the series of articles dealing with carbon miniatures on ivory, carbon prints on wood, and one or two other applications of the process. (P. 135.)

**Practical hints on photographing dogs** have been recently published by Mr. Thomas Fall, whose firm of Baker Street has long been noted for this branch of work. (P. 143.)

**The Scottish Salon.**—Some notes on the professional work appear on p. 144.

An editorial draws attention to the literature which should form the reading of a student of stereoscopy. (P. 134.)

A curious outcome of the present enthusiasm for co-operation among photographic societies is mentioned in the opposite column.

An interesting case of markings on negatives appears on p. 151.

Some further letters on professionalism in photography appear on p. 150.

An automatic shutter release is among the patents of the week. (P. 145.)

The Rev. H. W. Dick's method of systematising ozobromes is noted on p. 146 from this week's "Amateur Photographer."

Sir Henry Treman Wood asks for scientific exhibits for the photographic section of the Franco-British Exhibition. (P. 149.)

The case of a photographer who was heavily mulcted in damages for opening an assistant's letter is reported in "Commercial and Legal Intelligence." (P. 149.)

## EX CATHEDRA.

### Federation and Affiliation.

The combination and co-operation of photographic societies is being much talked about just now, but some of the opinions that are being expressed seem to show very strange ideas as to the advantages of federating or combining. Some time ago we pointed out in an "Ex Cathedra" note that a society that filled its programme with affiliation or federation lectures could not be considered to be in a very healthy condition. Neither did it show an appreciation of the proper use of co-operation. We now see that one unfortunate society that fills its programme with home-made lectures is being severely dropped on for being "parochial." Because out of fourteen subjects announced no less than eight are by local lecturers and only one by an outsider, this society is urgently recommended to join a "union" and make use of "union lectures" and "union lecturers." Apparently this society is prosperous, and its "parochial" lectures seem to be good ones. So far as we can see, it has no need whatever of bringing in outside lecturers, and, judging from the argument used, it seems to have very much less need for the Union than the Union has for its "parochial" lectures, which appear to be looked upon with a certain amount of envy. For our own part we have great respect for a society that can stand alone, fill its own programme, and be prosperous without the aid of "co-operation." If it cares to federate for the purpose of helping on the weaker societies, well and good; but it is absurd to blame it for being self-supporting. A very absurd development of the mania for federating is a proposal for the formation of a "British Photographic Association" that is apparently to include all existing societies. Setting aside the obvious impossibility of bringing all the existing societies into line on this proposal, it is pretty clear that the result would be a failure. We cannot imagine any possible benefit from such an organisation, and it is certain that new independent societies would immediately be formed to accommodate those who dissented from the Association.

\* \* \*

### Control in Sulphide Toning.

An article on another page by Mr. H. T. Munkman describes some interesting experiments on the conditions governing the tone obtained by sulphide toning. The conclusion arrived at is that the exposure and development of the bromide print are practically the only factors of consequence. Many other workers have, however, claimed that modifications can be produced by varying other conditions. As regards the bleachers, all those mentioned by Mr. Munkman may be described as simple bleachers; that is to say, they convert the silver into a silver salt without depositing any appreciable quantity of foreign compounds in the film. Others, such as bichromate with

a very little hydrochloric acid, or ozobrome solution, leave a fairly substantial deposit in the film, and our experience is that this deposit may appreciably affect the final colour. It is on account of this deposit that the colour obtained by using soda sulphide after bichromate and hydrochloric acid is generally less pleasing than that produced when ferriyanide and bromide forms the bleaching solution. Mr. Munkman refers to the use of pure sulphide. As a rule the sulphide used is very impure, and the tone it gives may be quite different from that produced with the pure compound, and still not be displeasing. We have obtained very good tones with a solution of commercial sulphide that has been boiled and filtered, and these tones are generally of a purer brown tint than the purplish tones produced by nearly pure sulphide. Probably the two conditions that we have mentioned have a good deal to do with the variable colours produced by different workers, but possibly also the brand of paper used affects the question to some extent. We have often experienced a difficulty in producing a strong tone on a very glossy paper, while some matt papers have shown a tendency to give an unpleasantly dark shade of colour.

\* \* \*

#### **Distortion in Lenses.**

In our last issue Dr. Zschokke criticised the recent article by Dr. Wandersleb on "Distortion in Symmetrical and Unsymmetrical Photographic Objectives." Dr. Zschokke takes special exception to Dr. Wandersleb's statement to the effect that symmetrical lenses are almost universally looked upon as necessarily free from distortion. Dr. Wandersleb, however, only stated that this idea was generally accepted "amongst photographers." This is undoubtedly the case, and the contrary is not proved by quoting the opinions of expert opticians, nor yet by making the impossible assumption that Dr. Wandersleb is ignorant of their opinions. We certainly consider Dr. Wandersleb's work on this subject to be of very great value, and anyone who makes a careful and unbiassed study of his full paper in the "Zeitschrift für Instrumentenkunde" and of the numerous diagrams that it contains, will, we believe, come to the same opinion. It is certainly of advantage to photographers to know that there are numerous symmetrical objectives that are not, strictly speaking, corrected for distortion at all. They are free from distortion when used for copying on a scale of full size just because, and only because, they are symmetrical. This condition is fulfilled automatically, and, as Dr. Wandersleb says, "without any assistance on the part of the constructor." The familiar R.R. lens is an example of such an objective, and in it no attempt whatever is made to "correct" distortion; if, however, a symmetrical objective is to be free from distortion when used in new symmetrical conditions then special correction methods must be applied. This is where the trouble actually comes in, for the optical condition that has to be fulfilled to correct distortion is opposed to that governing freedom from spherical aberration, and the attempt to correct for both aberrations at once leads to complications, especially with lenses of large aperture. Readers interested in this matter should study Chapter VI. of Lummers' "Optics," the translation by Dr. S. P. Thompson. Seeing that lenses are commonly used in unsymmetrical construction, many favour the attainment of an ideal freedom from distortion in practical working conditions, and this appears to be the view that Dr. Wandersleb wishes to convey.

#### **The Photography of Noise.**

An apparatus for recording speech by photography has been constructed by Dr. Marage, of Paris, but the practical use of it is not yet apparent. Perhaps, however, it may be the forerunner of an instrument that is very much wanted

—that is, one for recording noise. Pretty well everything else can be recorded automatically by the aid of photographic instruments, but as yet there is no way of accurately recording noise at all, though a method of accomplishing this purpose would be of considerable value. At present there is only one very rough and unreliable method of measuring noise, and that is by placing reliance on the evidence of people whose nerves are fairly tense on account of it. Noise is bearable and harmless up to a certain limit, but beyond that limit it is unbearable and injurious, and there is no exact way of determining when the limit is reached. Economy makes it almost certain that photography must play a part, for a pencil of light and a piece of white paper form the cheapest writing instruments that can be used. The rest will be more or less a problem of mechanics, and as many photographers have shown aptitude in this direction, there is no reason why a photographer should not solve the problem. The main difficulty is, of course, that of rendering the instrument sensitive to trivial or pleasing sounds and only sensitive to discordant noises, but this should not be insurmountable.

#### **THE ENGLISH LITERATURE OF STEREOSCOPY.**

THE stereoscope being essentially an English invention, the English literature bearing upon the subject is of great interest, but owing to somewhat peculiar circumstances very few students probably know which are books of special importance. The modern books are nearly all foreign, and some of them have the fault of dealing with the subject on a purely mathematical basis, whereas as we have before pointed out, is misleading, and of little real value. The older books, with a few exceptions, are not this fault, and our experience has been that these are the books that are most suggestive of the true theory of stereoscopy.

These books may be divided into three classes. The first includes books upon the stereoscope and its theory; the second, books upon binocular vision, many of which have a most important bearing upon stereoscopy, though not devoted to the subject, and in many cases not even mentioning it. The third class is a somewhat remarkable one, to which it is difficult to find an exact parallel in other branches of science. It includes books treating upon stereoscopic vision, but written before the stereoscope was invented. Many of these books are quite disregarded by students, some because their titles convey no indication of the fact that they are valuable sources of information on the topic, and others because they were written long before the stereoscope was thought of, and are, therefore, probably thought to be useless. In the first class there are three very important books that no one should fail to study. These are by Brewster, Wheatstone, and Le Conte. The first, Brewster's "The Stereoscope," 1856, is the "classic" book on the subject, but it requires to be read with caution, as it contains many assumptions that will not bear investigation. Of equal importance are Wheatstone's papers, to be found in the "Philosophical Transactions" of 1838 and 1839, and in Wheatstone's "Scientific Papers," published in 1879. Le Conte's book is called "Sight," and was published in 1881. His ideas are original and most important to study; but we fear many neglect both Wheatstone and Le Conte, though both books are easily obtainable. These are the three most important English books dealing directly with the theory of stereoscopy, but Chadwick's "Stereoscopic Manual" and Brown's "Stereoscopic Phenomena of Light and Sight" should also be studied.

In the second class, a very old book of some importance is Harris's "Optics," 1775. This contains some notes and experiments on binocular vision that are very suggestive

Another is Coddington's book of 1830, forming Part II. of his "System of Optics," and entitled "On the Eye and Optical Instruments." Dr. Young's "Lectures" should also be consulted. There are also, of course, numerous modern books on the eye that deal with binocular vision, but perhaps the most important book on the subject is not in English but a French one, Professor Tscherning's "Physiological Optics." Another very important old book is Berkeley's Essay on Vision, the second edition of which was published in 1709.

In the third class there are two most remarkable books. The first is Dr. Smith's "Opticks," 1738, which includes Dr. Brewster's essay upon "Distinct and Indistinct Vision." No writer is so frequently quoted as Dr. Smith in reference to stereoscopy, though his book was published just one hundred years before the earliest of Wheatstone's papers. His experiments are classic, and should be studied first and foremost. The next is an even more remarkable book, Dr. Brewster's "Essay on Single Vision," which includes sundry experiments and observations on optical subjects. This was published in 1792 in one volume, and again in 1818 in a collection of "Papers." We have referred to this essay before as one that must not be neglected.

The books mentioned by no means exhaust the number of those to which reference may be made. Some of the most important facts with regard to the manner in which we see solid objects were elucidated as far back as 1613 by Aguilonius (or François d'Aguillon), and his theories are very well worth study at the present day, and we may even with advantage go back to the works of Galen and Euclid. We have not endeavoured to exhaust the subject, only to call attention to the more important English books upon it, some of which are very commonly neglected, and apparently almost unknown. We should also consider Brewster, Wheatstone, Le Conte, Dr. Young, and Dr. Wells as essential to students, while Dr. Smith, Harris, and Coddington should by no means be neglected. Few libraries possess all these books, but they can be bought secondhand at very low prices. Coddington is extremely rare and difficult to get, though low in price, but numerous copies of the others are to be obtained, and only last year we obtained the complete set for a total expenditure of £2 7s. 6d.

In connection with stereoscopy, the "B.J." should by no means be neglected. From the earliest days of the Journal this subject has received much attention in its pages, and a very notable and valuable contribution was made by Mr. R. H. Bow in 1864, consisting of a series of five articles on the stereoscope and stereoscopic vision.

A very important point to remember in connection with the literature of stereoscopy is the fact that even now the theory is by no means firmly established, and that there are many facts concerning it that as yet have no possible explanation. In any scientific subject it is never safe to trust entirely to one text-book or one authority, and in stereoscopy it is not safe to place absolute reliance on any. One very important error that is to be found in nearly all the books mentioned vitiates a great many of their arguments. This is the statement that "distance is seen as perfectly by children as by adults," as Brewster puts it. At the present day no doctor will admit this to be true, yet the effects that the blunder has had on the theory of stereoscopy still have a great influence. Its most important effect has been the creation of the idea that our appreciation of distance and solidity depends entirely on a kind of involuntary mechanical process. The fact that we have to learn to see just as we have to learn to walk and use our hands has been ignored, but it is the most important fact that has a very distinct bearing upon the problem of how we see distance and solidity in the stereoscope.

## PROFITABLE FORMS OF CARBON PRINTING.

### IV.

In the previous articles\* of this we have dealt with certain special applications of the carbon process which may prove remunerative to professional photographers. We must now conclude these chapters by giving the necessary instruction for the preparation of photographic prints on ivory, which can be worked up and coloured to any necessary extent. Ivory, we may explain, is a material which is not readily amenable to sensitising by a silver print-out process, and carbon is practically the only way of producing the base, on which the artists' work is done, or, if preferred, of giving a pigment picture alone. This and one or two other less known uses of carbon will now occupy us. Before describing the method, it is as well to say at once that the pictures must be made by the double transfer process, as if attempted by the single process the ivory would be stained by the bichromate in the tissue, and the stain could not be got rid of. The ivory used must be free from scratches, as it usually is when purchased from the dealers in artists' materials, but if it is not the scratches must be removed. This is done in the following way: The ivory is wetted with water, and a little very fine cuttlefish powder sprinkled over it. This is then ground over with a piece of cork, used as a muller, until the scratches are removed. After washing and wiping dry, the ivory is ready for use. The print is developed in the ordinary way on flexible support, alumed, and allowed to dry; it is then ready for transferring to the ivory, which is done as follows: A solution is made:—

Nelson No. 1 gelatine .....	1 ounce.
Water .....	1 pint.
Chrome alum in 1 oz. of hot water ...	12 grains.

This solution, kept at a temperature of about 140 deg. to 150 deg. Fahr., is put into a deep dish, and the picture on the support—which should be trimmed a little smaller than the ivory—is then introduced together with the ivory. After soaking for a minute or so, the two are brought into contact, removed, then squeezed together, and allowed to dry. When dry the flexible support is stripped off, and the surface of the picture rubbed over with a plectrum of cotton wool charged with benzole to remove all traces of the waxing compound which, if left, would prevent the artist's colour taking freely. In making photographs on ivory for miniature painting it is desirable to employ a negative somewhat thin and delicate in character. The tissue should contain a liberal proportion of colour, so as to get an image in as little relief as possible, since a high relief gives trouble to the artist in the finishing, and may possibly show in the finished picture. If the picture is to be highly worked up it is well to consult the artist who is to do the work, as to whether a light or an ordinary depth picture is preferred, and also as to the colour. We knew an artist some years ago who, when he had a silver photograph to finish as a miniature, would not have the print toned beyond a warm red-brown. He said that saved him a deal of trouble in the colouring when the picture was to have the higher finish.

Photographs on wood panels, for decorative purposes, might be made a profitable side line with some, and are not at all troublesome to produce. The wood should be of a light colour, or white. The surface may be made perfectly smooth with glass paper, working the latter always in the direction of the grain and finishing off with paper of the finest grade. The panel is then coated with the solution given above, which is applied fairly hot with a camel-hair brush. Two coatings will be necessary—the

\* "B.J." January 17 and 24, and February 7.

first to fill up the pores of the wood, the second to give an adhesive surface. With very porous wood three coatings may be required. The print is made on flexible support in the ordinary way and allowed to dry. To transfer it to the panel the coating on it is sponged over two or three times with tepid water to soften the gelatine slightly. The print on its support having been trimmed to size and shape, is put for a minute or so in the above solution, which should be made tolerably hot—170 deg. to 180 deg. Fahr. It is then laid in position on the panel and well squeegeed to it. When dry the temporary support is removed. The picture should then be varnished, or, better still, French polished, but before the polishing is commenced it will be well to give the panel a thin coat of a white varnish—such as a lac negative varnish. This will protect the picture from injury in the first stage of the polishing. It is needless to say that white French polish must be used for the work. Should the panel become warped during the operation it can be straightened when the picture is finished. If the reverse side is curved inward the back should be evenly sponged over with water and the panel put under pressure for a few hours. If it is outward the back is placed, at some distance, in front of the fire until it straightens out, then put under pressure for a day or so. But if the wood is well seasoned, as it should be, warping is not likely to occur.

Some little while back the method of enamelling silver prints with collodion was fully described in these columns. It is, however, far more troublesome to enamel silver prints than to produce enamelled carbon ones. Indeed, carbon is the easiest of all methods by which to produce enamelled photographs, while there is no question as to the stability of the pictures. A glass plate, after being waxed or rubbed over with French chalk, is coated with thick enamelling collodion. When this has well set the plate is put into cold water until all traces of the ether

and alcohol are washed away. The exposed tissue is then mounted as if it were ordinary flexible support, a piece of thin mackintosh cloth being laid over the plate to prevent the squeegee from tearing the collodion film at the margins. The image is then developed as usual and allowed to dry. When dry, the plate is put into water, a piece of softened double transfer paper is squeegeed upon it, and when dry, stripped off. We thus obtain a highly enamelled print without further trouble. If a second piece of transfer paper is squeegeed on, after the first has become surface dry, the picture is practically on thin cardboard.

Many photographers have a window with an unsightly outlook, or, possibly, a corridor that sitters have to pass through to the studio. This unpleasant outlook may be hidden by hanging in the windows carbon transparencies, portraits or landscapes—backed with ground glass, and framed in the light metal frames sold for transparencies. In this way an ugly outlook is converted into a pleasing and attractive one. As some customers may have window similarly circumstanced they may be induced to order transparencies to fill them. This would "bring grist to the mill" of the photographer.

Lastly, many may not be aware that the carbon process is utilised for the labels on druggists' bottles. The lettering is photographed to size so that when printed the letters show as white on a black ground. The negatives are made very strong. They are then printed in a dense black tissue and the image developed (single transfer) on the inside surface of a curved glass, of the same curvature as that of the bottle. The letters are then gilded, which need be only roughly done, and a gilded border put round. The curved glass is then cemented to the bottle, in a recess moulded for its reception. When the labels are produced in this way they are not injured by washing, scratched in the dusting, as the lettering or design is between the bottle and the glass.

## SOME EXPERIENCES WITH NEW METHODS OF SULPHIDE TONING.

HAVING had the opportunity of personally testing the effects of the two latest sulphide toners my experiences may be of some interest to readers of the "B.J." One of these new preparations is the sepia toner of Messrs. Burroughs and Wellcome, which is understood to be a thiostannate compound, while the other is the thiomolybdate sepia toner, worked out by Mr. H. E. Smith, and introduced to photographers by Messrs. Edmund and Co. Apparently the bleaching solutions sent out with the two toners are the same in all essential respects. Both seem to consist of the well-known mixture of potassium bromide and ferricyanide commonly used with sodium sulphide as the toner. The toning solutions are, however, essentially different, not only in composition but in effect. They give quite different colours and the thiomolybdate toner is capable of producing quite a long range of browns, all of which are distinctly different from the brown given by the thiostannate.

### Thiostannate Sulphide Substitute.

I tested the solutions in parallel conditions, comparing the results with each other and with the tones obtained by soda sulphide. Stating the results generally, I found that the thiostannate gave a tone closely resembling that produced by commercial soda sulphide when working at its best. That is to say, it is a soft brown very nearly approaching to sepia. As regards the advantages of the thiostannate over sodium sulphide they are fairly obvious. The smell of sulphuretted hydrogen is not nearly so strong, and a good colour is obtained with far greater certainty. Though much the same shade of brown is

produced as with the commercial soda sulphide the quality may be described as better. It is less inclined to be yellow, and is rather purer and stronger brown. It is a good brown, whereas the other is generally a bad one, and a remarkably fine rich effect is produced when the result is glazed.

### The Thiomolybdate Toner.

The results with thiomolybdate are quite different from those with thiostannate. The brown is of an altogether different kind, and the varieties obtainable may all be described as varieties of what photographers know as "photo-brown." Used in a certain way, the toner gives a capital imitation of the purplish tone of the best commercial hypo-alum toned prints.

The colour varies markedly with the time of toning, and the standard time of 5 minutes recommended by Mr. Smith results in a colour that when glazed can easily be mistaken for that of a brown gold toned P.O.P. print. It is a much richer and redder brown than the ordinary sulphide tone, and the image appears to be intensified to a certain extent. If only treated for 2½ minutes a slightly colder tone is obtained, while if the toning is prolonged for 20 minutes a browner—that is, less red—tone is obtained. The application of a strong hyposulphite bath has a similar but somewhat more marked effect, and this tone may be described as a brown midway between the thiostannate brown and the normal thiomolybdate colour.

### Reducers and "Sulphide" Tones.

All the tones obtained by sulphiding processes are amenable to reduction, and a strong Farmer's reducer, such as that used for

graph, has a very marked effect on the ordinary sulphide brown, or on the thiostannate brown, the effect of reduction is production of a very unpleasant yellow brown. The thiomolybdate "photo brown" is, however, changed to a simple brown of a good tone if the reduction is not carried too far. As to the effect of intensification before noted, the thiomolybdate prints will stand more reduction than the others, but the process must always be somewhat risky.

#### Thiomolybdate and Modified Bleachers.

The most striking changes of colour are, however, produced by intensifying the bleaching solution. It is well known that the ordinary sulphiding process can be modified by similar variations, but, unfortunately, no bleacher seems to give quite such satisfactory tones as the ferricyanide and bromide bath. The trouble is to get strong tones with soda sulphide, and the common fault of other bleachers is the production of weak, powdery browns. The thiomolybdate brown is, however, usually a very strong one, therefore, the bleachers that fail with sulphide may prove of value with the new reagent, especially where its intensifying action is not required. A very useful soft brown of great depth and transparency is produced if potassium bichromate is added to the bleaching bath, if ozobromine solution is used in place of the ordinary bleacher.

For a portrait, or similar subject, in which fine modelling and gradation must be preserved this appears to be an ideal bleaching method, and I can strongly recommend it. The tone is exceptional, and the brown is one of a kind that I never expected to get by way of sulphide toning.

Another bleaching bath also gives very striking results. This is a solution of mercuric chloride, which is quite useless for the soda sulphide or thiostannate toners as the resulting tones are black. The thiomolybdate toner, however, gives a very rich purplish

red brown. In using this bleacher the mercury should be followed by a soaking in weak hydrochloric acid, and this again must be followed by very complete and thorough washing, otherwise the whites will be badly stained.

All these toners work as well on gaslight papers as on bromides, but, like all the sulphiding processes, they tend to produce clogged-up heavy shadows on matt surfaces. This can, of course, be remedied by glazing, or waxing. The tones vary somewhat on different types of paper, and it does not seem possible to obtain the same depth of tone on a very glossy paper as on one of ordinary surface.

#### A Field for Further Experiments.

Many variations of method are possible, and in one case I attempted to intensify a rather weak print toned with thiostannate by treating it with mercuric chloride and thiomolybdate. The result was a rather striking strong red colour. Evidently the thiomolybdate solution offers possibilities in the way of intensifying weak toned prints, but the best way of so employing it is a matter for experiment.

It is worth mentioning that the thiomolybdate toner gives off hardly any sulphuretted hydrogen, and even when it has been in use for a long time the odour can barely be detected. After toning, the whites are generally slightly stained, but this stain washes out in from 20 to 30 minutes under the tap. When bichromate is used in the bleacher the print must also receive a good washing between bleaching and toning. The fine colour obtained after this bleacher is no doubt partly due to the presence of chromium and iron compounds in the image, and the softness of the result is probably due in part to the fact that in the presence of these compounds toning does not go so far as usual. The difference in contrast between results produced by this method and by the standard method is very striking.

C. WELBORNE PIPER.

## A NOTE ON REDUCERS FOR SEPIA-TONED BROMIDES.

(A Paper read before the South Suburban Camera Club on Wednesday, February 12.)

HAVING been asked by our energetic secretary to put together a short résumé on the subject of reducers for bromide prints toned with sepia by the sulphide process, I felt at the outset troubled by the difficulty that, although I try to make my photographic reading as wide as time will permit, I have very likely missed something that has been published on the subject, and, having done so, I can only say that I have included everything that I have found any reference to. I think that Mr. E. J. Hall was the first to mention that sulphided sepia prints could be to some extent altered. He did so when giving results of his experience with sanzol (the cobaltamine reducer) in "The British Journal of Photography" of February 2, 1906. The "British Journal" for February 16, 1906, in referring to Mr. Hall's article, mentioned that silver mono-sulphide is somewhat readily chlorised, and in its issue for March 9, 1906, stated that black silver mono-sulphide, prepared by precipitation from silver nitrate, was chlorised by potassium bichromate and hydrochloric acid, readily iodised by a solution of iodine in potassium iodide, and very rapidly attacked by bromine water; so, that it was found to be slowly affected by a solution of potassium ferricyanide and potassium bromide, while Farmer's reducer, ammonium persulphate, and chromic acid, all dissolved away from the black sulphide.

#### Reducers of Silver Sulphide Images.

We therefore owe to the "B.J." the fact that the sulphided image can be readily converted into a halogen salt of silver, and had I not most unfortunately missed the note in the

"British Journal" for March 9, I do not suppose that I should have done much work on the subject. However, in the "Photographic Journal" for June, 1907, having at that time been experimenting in this direction, as I had accumulated a number of over-dense sepia prints, I recommended some reagents for reducing sulphide-toned sepia prints, and I placed them tentatively in the following order of merit:—

1. Cupric chloride, and sodium chloride in aqueous solution.
2. Cupric bromide in aqueous solution.
3. Cupric chloride in aqueous solution.
4. Chlorine water.
5. Bromine water.
6. Iodine in aqueous solution of potassium iodide.
7. Iodine in aqueous solution.
8. Iodine in alcohol.
9. Solution of potassium permanganate acidified with sulphuric acid.

#### Farmer's, Cyanide, and Other Reducers.

I did not mention Farmer's reducer or the mixture of potassium bichromate and hydrochloric acid, as I was not aware at that time that they were of use, and had not tried them. I should not have put chlorine and bromine water fourth and fifth on the list but for their pungent odour, or iodine further down the list had not the formation of the blue iodide of starch in the print been somewhat troublesome, as it renders it in some cases a little difficult to judge of the true extent of the action at any given moment. Other references to

reducing sulphided bromide prints that I have seen are the following:—Mr. J. D. Kettle, in the "Amateur Photographer" for July 23, 1907, recommended potassium ferricyanide and sodium chloride for bleaching the sulphided image for re-toning.

I mentioned in a letter to the "Photographic News" for August 2, 1907, that a print that was too dark a sepia tone on drying might often be corrected by again treating with the ferricyanide-bromide bleacher for, say, five minutes, and then placing a second time in the sulphiding bath (the bleaching solution should, of course, be washed out before re-sulphiding). The result is generally a rich and much warmer tone. A correspondent writing to "The Photographic News" of August 23, 1907, recommends as a satisfactory method of reduction, to place the print in a hypo-alum bath, and heat, as one would treat a black bromide print by this process. The colour is stated to be if anything improved.

The Editors of "The Photographic Monthly" for September, 1907, mentioned the fact that they had been in the habit of using potassium cyanide for reducing sulphided bromide prints; and in the same number I called attention to the fact that sepia bromides that had been toned to a red chalk colour with a gold sulphocyanide bath, could be reduced with the copper chloride and sodium chloride mixture.

Regarding the solubility of silver mono-sulphide in potassium cyanide, three references that anyone interested might care to turn up are: (1) Hahn, "Chemisches Centralblatt," 1870, 240 (this reference is at the beginning of the third series of nineteen volumes); (2) Béchamp, "Journal für Praktische Chemie," 60-64; and (3) "Journal de Pharmacie," third series xxiii.—413. Hahn gives particulars of the treatment of an ore containing silver sulphide with potassium cyanide, with the amounts of silver left in the residues after the bulk of the sulphide had been dissolved. Béchamp states that, while silver sulphide had been held to be insoluble in potassium cyanide, and is in fact difficultly soluble, if precipitated, for instance, from a concentrated solution; on the other hand, if the silver sulphide is precipitated from a very dilute solution potassium cyanide dissolves it completely, and the liquid is quite colourless. The relative proportion of potassium cyanide present also is of importance. It is, therefore, evidently owing to the finely divided state of the silver sulphide compound in sepia prints that potassium cyanide can be used to reduce them.

Of the reducing agents mentioned, I am inclined to think that the cupric chloride and sodium chloride mixture is one of the best, as this, while reducing with satisfactory rapidity, only very slightly affects the tone of the print, and, moreover, can be used with advantage on the "red chalk" gold-toned sepia prints. In my experience it will reduce these without spoiling the red tone, while a reducer that I have quite recently tried, and refer to below, though it is more energetic in action, is apt to spoil the tone of the "red chalk" prints.

#### Residual Copper in Sepia Prints.

With regard to the question of copper being left in the print after reduction with the copper chloride and sodium chloride mixture, and fixing and washing the print, I have analysed a 12 in. by 10 in. sepia bromide reduced in this way, and found a small amount of copper. A very small amount of copper seems liable to give stains in the print when it is subsequently treated with the sulphiding solution, and therefore in this case I recommended (in the "Photographic Journal") that the copper should be cleared with dilute nitric acid first. Where these reagents are used for reduction only, however, I believe that a nitric acid bath is quite unnecessary.

If we were dealing with the black silver image with the cupric chloride mixture, we should no doubt have cuprous chloride left after reduction, which, though insoluble in water, is soluble in hypo (Clemens Winckler, "Journal für Praktische

Chemie 88—428), so that, after fixing and washing, we should have no copper left in the print. I have analysed one 12 in. by 10 in. black bromide print so reduced, and was unable to detect the presence of copper. I should be glad to see this confirmed.

We are, however, dealing with the sulphided image, and appears that in this case copper is left in the print as a sulphide, and I have recently found a reference to the action of cupric chloride and sodium chloride on metallic sulphides viz., Raschig ("Journal of the Chemical Society Abstracts," 1884-96; "Bérichte," 17, 697-698; and "Liebig's Annalen," 228, 1-28), whence it seems that the silver sulphide with cupric chloride and sodium chloride yields silver chloride and copper sub-sulphide. I think that we may assume; then, that the copper in the reduced sepia print is in the form of cuprous sulphide, and, since the copper is present as a sulphide, and moreover, cuprous sulphide is the more stable of the two copper sulphides (Watt's "Dictionary of Chemistry," II., 261), it does not seem to matter whether it is left in the print or not, as it is unlikely to affect the permanence of the image.

Indeed, there seem to be few solvents of cuprous sulphide. Most reagents that attack it require the aid of heat. Indeed only nitric acid seems to attack it in the cold, dissolving only copper and leaving cupric sulphide, so that when we clear a print with nitric acid, it seems likely that we do not remove all the copper, which brings us back to the old question: Are the reactions on the very finely divided compounds in a print the normal ones? To a large extent they seem to be similar, but it would appear that only a series of quantitative analyses of the toned and reduced prints can clear the matter up satisfactorily, and the analyses that I have found time to make so far show me that it would be no light matter.

#### A Formula for Practical Work.

Referring again to the new reducer that I mentioned for these sepia prints, it is:—

Cupric bromide .....	3 gms.
Sodium bromide .....	25 gms.
Water .....	100 ccs.

I find that this bleaches a sulphided print almost as readily as the ferricyanide-bromide mixture does a black silver print. The formula I have given may well be diluted with three parts of water for use, as it is rapid in action when used for reducing only. I have made a qualitative analysis of a 12 in. by 10 in. sepia print reduced with the cupric bromide mixture, and when the copper was separated I judged it to be considerably less than the amount obtained from the print reduced with the copper chloride mixture: judging, that is, from the bulk of the precipitate and also from the bath of the coloration on adding ammonia in excess, after dissolving the precipitate in nitric acid. The print analysed in this case was of the same subject, and as nearly as possible of the same density, as the one that I analysed after reducing with the copper chloride mixture; so that the results might be comparable, but, of course, an enlargement from a negative of graded scales would be much better, the enlargement after toning being accurately divided, and the two halves treated respectively with the chloride and bromide mixtures. I have very recently made some bromide enlargements in this way, for quantitative analysis, but have no results ready at present. I am not quite sure that a very little copper may not be volatilised in the burning off of the print and ash before analysis, but this should apply equally to both prints.

Regarding this cupric bromide mixture, I have searched without success for a reference to a cupric sodium bromide, after the type of the double salts that cupric chloride forms with potassium chloride, for instance, so that unless I have missed the reference I presume that no definite compound salt of this type can be formed in this mixture. The deep reddish

purple colour that may be observed on evaporating and crystallising this mixture is perhaps owing to the formation of a hydrobromide, as described by Sabatier ("Comptes Rendus," 118, 980-983).

To conclude, then, I should recommend for general efficiency in reducing bromide prints this cupric bromide mixture, and for the "red chalk" gold-toned variety, the cupric chloride mixture.  
HARRY E. SMITH.

## ON CONTROLLING THE SHADE OF SEPIA PRODUCED BY SULPHIDE TONING.

The sepia produced by the sulphide method of toning bromide prints vary from a very warm to a cold and almost black shade. So far as I have been able to ascertain, no one has given any directions which would enable a worker to produce any given shade of sepia. It would appear that the difference in final colour must arise in the emulsion, the negative, the exposure, the developer, the development, the bleaching agent, or the sulphuretting agent, and it was with a view to ascertaining which of these determined the final colour, and to what extent, that the following experiments were made.

Bromide papers of several makes were exposed behind a graded negative. These papers were developed, fixed, washed, and bleached, various bleachers being used, and various developers. Each strip was then cut into two pieces, the one sulphuretted in a strong solution and the other in a weak solution of sodium sulphide. The weak and the strong sulphuretting agents produced identical shades of sepia in each pair of papers. It is evident that if sodium sulphide be used the strength of the solution has no effect on the ultimate colour.

### Various Sulphiding Baths.

Strips were similarly identically treated up to the sulphuretting stage and were then cut each into three portions. These were sulphuretted in a solution of sulphuretted hydrogen, a solution of ammonium sulphide, and a solution of sodium sulphide respectively. The colours of each set of three proved to be again identical. It would therefore appear that the sulphuretting reagent, provided it be pure, for an impure sodium sulphide may produce a reduced and unpleasant yellow-brown image, is not a factor in determining the shade of sepia.

### The Bleaching Bath.

Various makes of papers were exposed behind the graded negative, developed, fixed, and washed together. They were then cut into strips and thoroughly bleached respectively in the baths consisting of potassium ferricyanide and ammonium bromide, potassium ferricyanide and potassium bromide, potassium ferricyanide and sodium chloride, potassium ferricyanide and ammonium hydrate, potassium bichromate, sulphuric acid and sodium chloride, copper sulphate, sulphuric acid and potassium bromide, each made up according to various published formulæ. These bleached strips were washed (the ones from the copper bleacher with the aid of dilute acid) and sulphuretted, and, though a little difference in shade of sepia was to be observed, it was not sufficient to be of any practical import. Strips were also treated with the usual iodine bath, cleared, washed, and sulphuretted, but showed no useful difference in colour.

Similarly prints cut and the one half bleached in strong solutions and the other in dilute solutions showed identical shades of sepia on finally sulphuretting.

It is therefore evident that neither the strength nor the composition of the bleaching solution has any useful effect on the final colour of the toned print. With certain bleachers, notably the ferricyanide and ammonium hydrate one, which converts the metallic silver to silver ferrocyanide, some reduction is apt to take place; and, when this is the case, an unpleasant yellow-brown image is given.

It is a well-known fact that the less completely the silver image is bleached the darker is the sepia obtained, and this

was fully borne out by experiments. I cannot, however, think that such a method of determining the final colour can be advisable, since the image will consist of a mixture of metallic silver and silver sulphide in the shadow parts of a print, and wholly of sulphide in the lighter half-tones. If this method is adopted the bleaching solution must, of course, be dilute, so that its action may be readily stopped at any desired point.

### Is it the Negative or the Developer?

Some workers hold that the "tone" resides in the negative, and, though this is usually said of P.O.P. toning, I have heard it remarked in regard to the Blake-Smith process for bromides. Papers were cut and exposed behind different portions of the negative, and proportionate exposures given, so that when developed out together equal densities were obtained. On toning these, identical colours were secured. Papers were also cut, and one portion exposed for a short time to a strong light, the other halves for a correspondingly longer time in a weaker light—i.e., further away from the source of light. These were developed, fixed, washed, and toned together, and gave no difference. These experiments prove that neither the negative nor the speed of printing has any influence on the final colour; though, of course, this is not the same as saying they have no effect upon a print, since they would alter the steepness of gradation, and consequently the general appearance. The mere colour, however, would be the same whatever the negative, and whatever the speed of printing.

Papers were exposed, cut into strips, and developed out in amidol, quinol, metol-hydroquinone, rodinal, glycin, and other developers, each of standard strength. After the subsequent operations they exhibited no difference of colour. Exposed papers were cut, and one half developed quickly in a standard solution, the other developed out to the same density in a dilute solution. After toning the slips developed in the dilute developer showed a slightly but distinctly colder shade of sepia. On similarly testing the effect of cold and warmer developers it was found that the slips developed in the cold reagents gave slightly colder sepia than the others.

Similar strips were developed in amidol without any potassium bromide and in amidol containing bromide. The former gave colder sepia than the latter, and within limits, at any rate, the greater the proportion of potassium bromide the warmer the sepia finally produced. Since, however, the increase of potassium bromide results in the destroying of the lighter half-tones in a print from a negative suitable for the process, this would not afford any practical means of control.

### Differences due to Exposure and Development.

Papers were cut and exposed so that strips received successively increased exposures. The strips were then developed so as to produce prints as nearly alike as possible; and, on completion, it was found that the greater the exposure the warmer the final colour. It is, of course, well known that an over-exposed print only yields an unsatisfactory yellow "toned" image, but it would also appear to be a fact that the warmth of the image, when a satisfactory sepia is obtained, depends upon the degree of completion to which development is carried. Sheets from the same batch were exposed behind a landscape negative for 30, 32, 34, 36, 38, and 40 seconds. They were then developed as in ordinary practice, and gave fairly uniform and satis-

factory results when developed and fixed. These were bleached, washed, and toned together, and yielded colours which ranged from a beautiful cold sepia to a distinctly warmer sepia with no suspicion of yellow. Various papers were given minimum exposure through an architectural negative and developed out with exceedingly strong developers (some with equal parts rodinal and water). After toning they gave a shade which could only be called a warm black.

The chief means of control of the shade of sepia in the toned

print would appear to be the due regulation of exposure and development. The less the exposure and the more forced development the colder the sepia finally produced.

With such an exposure as will produce a properly developed print after two or three minutes in any developer of full standard strength, any good bromide paper upon the market will certainly give a rich dark sepia. Different makes of paper vary somewhat in the warmth of the sepia produced.

H. T. MUNKMAN, M.Sc.

## P.O.P. PRINTS—NOTES CONCERNING THE NATURE OF THE IMAGE.

If a print on P.O.P. is plainly fixed (or toned and fixed, for that matter) and then, after washing, bleached with a suitable bleaching solution and afterwards sulphuretted, the sulphuretted image will be found to be very faint—much fainter than the original one. Now, it might be said that the reason for this is that the silver forming the image of a P.O.P. print is of a molecular structure giving great covering power, and this structure is not passed on to the sulphide. There is, however, no reason whatever why silver sulphide should be imagined not to equal the silver from which it is formed nearly or quite in covering power. Certainly, there is no instance known in which there is much, if any, difference. The difference in strength of the image in the above quoted case is so great as to rule out a merely physical explanation altogether.

The image on a plainly fixed P.O.P. print consists of a "lake" composed of silver and silver chloride, and not merely of metallic silver. Like other similar silver chloride "lakes," this body possesses great covering power. I use the term "lake" here and elsewhere in this article to mean a molecular compound or solid solution. I am aware that many think the term should apply only to those molecular compounds produced by the combination of a dye with a metallic hydroxide. We can readily understand that the great loss in covering power is caused by the sulphuretting agent sulphuretting the whole of the silver halide and finally not leaving any over for the formation of a lake.

Of course, a theory assuming that the image consists of a mere mechanical mixture of silver and silver chloride would not explain the great covering power possessed by it. Moreover, such an image would be unstable in the "hypo" solution—all the silver chloride being dissolved out. We must, therefore, assume that some sort of molecular combination has taken place, or, as I express it, that a lake has been formed. In the "Amateur Photographer" for June 6, 1905, and in the four following numbers there were published some exceedingly interesting and important articles by Messrs. C. Welborne Piper and D. J. Carnegie, which all interested in this subject should read, if they have not already done so. Messrs. Piper and Carnegie showed how the gain in covering power by redevelopment was always accompanied by an increase in the halide constituents of the image. At the time I was rather sceptical about the theory they propounded that this increase in halide was the sole and only cause of the increase in covering power. I regarded the increase as mainly if not entirely due to molecular rearrangement of the metallic silver. What first made me alter my opinion was that I found that if a bromide print was bleached and redeveloped and then bleached again and sulphuretted the silver sulphide formed had exactly the same covering power as that formed by bleaching and sulphuretting the original image.

I also noticed that if a redeveloped bromide print was exposed to a solution of a soluble sulphide a slight action took place very readily and quickly. In the case of an ordinary primarily de-

veloped print, as is well known, no apparent action takes place for a very long time. The explanation here, of course is that the halide part of the image is converted into silver sulphide, though such images are stable in the presence of "hypo," they are not stable when exposed to sulphide solution. Messrs. Piper and Carnegie considered that the increase in "body" was due to the enlargement of the particles, which undoubtedly takes place as it naturally would. This is not sufficient, however, to account for the facts of the case and the formation of a lake must be assumed as stated above. Moreover, by bleaching an image we can increase the size of the particles and yet decrease the covering power. The presence of a halide of silver in a "silver" image can be directly detected by dissolving away the silver with a solution of ammonium persulphate or with a solution of nitric acid—the action of the latter being very slow. When all the silver has been removed, the remaining halide can be demonstrated by sulphuration or other suitable means. A better method, however, is to dissolve the whole gelatin film in 15 per cent. nitric acid and then heat the solution to boiling point, when all the metallic silver will pass into the solution, and an easily filterable precipitate of silver halide will be thrown down. By filtering off the precipitate, drying and weighing it, and then precipitating the silver as silver chloride from the filtrate, filtering, drying, and weighing that we can estimate the relative proportions of silver halide and metallic silver in the image. In the case of some of the images examined by Messrs. Piper and Carnegie, it was not easy to get direct proof of the presence of halides of silver, as these were present in such small quantity, but in the case of the image on a plainly fixed P.O.P. print there is no difficulty. I have found that the image on plainly fixed Barnet P.O.P. prints consists approximately of

Metallic silver .....	35 parts.
Silver chloride .....	65 parts.

The analysis was not very carefully done, and the composition of the image no doubt varies with the brand and condition of the paper to some extent. All I claim for my figures is that they show that the percentage of silver chloride is always very high in the case of all P.O. papers.

If a P.O.P. print be plainly fixed and washed, and then exposed to an atmosphere containing much sulphuretted hydrogen, or else to a weak solution of a soluble sulphide, the image changes colour, passing from brown through red and purple to a dirty bluish brown, and finally becoming very faint in density. At first the strength of the image seems rather to increase up till the reddish-purple stage is reached. The silver chloride, forming with metallic silver the lake of which the image is composed, is slowly converted into silver sulphide. It seems to me that to account for the colour it is absolutely necessary to assume that the silver sulphide forms a lake with the silver chloride. We cannot, of course, say whether we get a lake consisting of silver, silver sulphide, and silver chloride,

mixture of a silver and silver chloride lake and a silver sulphide lake. The red stage shows us an image in which much chloride remains, and the metallic silver and silver sulphide are both united with it in the form of lakes of good covering power. As the action proceeds, and the silver chloride gets more and more used up and converted into silver sulphide, the lakes get less marked in character, and possessed of less covering power, until finally the whole of the silver chloride disappears, and we get an image consisting of silver sulphide which is very meagre in substance.

I believe the red sulphide lake is the red constituent of all the red and purple tones on P.O.P. The opinion generally held is that the reddish tones on P.O.P. is that they can be obtained by sulphuration, but also by the deposition of red metallic gold. Now, I am quite well aware that metallic gold can be deposited from its solution in a red coloured form. I have, however, found that there never is any deposition of red gold on P.O.P. print, for in every case I have known over-toning of gold meant too blue a colour. If sufficient time is given in the toning-bath it is always possible to get this blue over-tone.

The toning-baths giving the reddish tones best, as a general rule, are certain "combined" baths and the thiocarbamide bath, when the latter is made up according to a suitable formula. The combined baths of any general use contain lead or an alum (or an alum), and these and the thiocarbamide bath, under suitable circumstances, slowly produce nascent sulphur. I imagine that part of the metallic silver is in this case sulphuretted just as the hypo-alum bath sulphurets the image of a silver print. Here, then, again, we get a red sulphide lake instead of a blue one. Now, what about the gold? Well, many things may happen. In the first place, there is a deposition of blue metallic silver, probably caused both by displacement of silver and also by the action of the sulphur. The solution of gold also reacts with the silver sulphide formed, as has recently been shown in the case of the thiocarbamide bath. The reaction is probably

the silver sulphide and silver chloride being formed. Of course, the fact that the silver sulphide is here part of a lake may make a difference, and we may get either very little action or no action at all. The aurous sulphide, if formed, may go into the lake, or may exist as a quite separate entity. It appears probable that the image consists of a mixture of the following (after the action in the case of the thiocarbamide bath, of course):—

Blue metallic gold.

A silver and silver chloride lake.

The red sulphide lake, i.e., a lake composed of silver sulphide and silver chloride or of silver, silver sulphide and silver chloride.

Aurous sulphide, either united with silver chloride in the lake or alone.

This is certainly a very complex affair.

Coming next in consideration the case of such toning-baths as the ammonium sulphocyanide (thiocyanate), potassium sulphate, or formate, we very often fail to get red tones at all. In every case in which the print is fixed for two minutes or more—which time is amply sufficient for fixation proper—the image will be found to be insufficiently red. The red character of the tone is gained during fixation, which it is necessary to try out with a solution of "hypo" of at least 15 per cent. concentration, and to continue for fifteen minutes or more. The change in colour while in the hypo solution may be due to a chemical change only, but I think it is almost certainly due to sulphuration. Why should this sulphuration take place in the case of prints toned with gold? The explanation is, I think, that the etching of the surface of the metallic silver particles caused by the action upon it of the gold leaves it in a state in which it is able to be sulphuretted by even a neutral solution of hypo. The uncertainty of the action certainly bears out

this etching theory, for we should certainly imagine that such a state of affairs would lead to a very uncertain result. Prints toned in a good thiocarbamide bath must not be fixed for too long, or they will fade. I advise only about four minutes. Here sufficient sulphuration has occurred in the toning-bath, as explained above, and further sulphuration beyond the red stage means destruction of proper density and good colour.

Nobody who has ever had any real experience of the toning of P.O.P. would ever guarantee to obtain always the same tone even approximately. If the tone was due to the deposition of red gold, and not to the formation of such an uncertain thing as the lake above mentioned, one would certainly expect far greater certainty. It is known that the colour of such molecular compounds as that spoken of above varies very greatly with even extremely small changes in their chemical composition. The action of a neutral solution of Schlippe's salt on bleached bromide prints shows this very clearly.

If any gelatine film is exposed to an acid solution of "hypo" containing too much lead or silver, the gelatine combines with the lead or silver to some extent, forming what Dr. Backeland has termed "retained" silver and lead. Even a neutral solution of hypo gives "retained" lead when it contains more than a very little lead. "Retained" lead and silver are colourless at first, but soon become yellow. The yellowing can be caused by the action of traces of sulphuretted hydrogen in the air, and by further action of the metallic compound on the gelatine. The yellowing of the whites of P.O.P. prints after keeping them a certain time is due to "retained" silver or lead, or to both. Where the emulsion contains soluble silver compounds, which is always so except in the case of Lumières' Actinos P.O.P., these soluble silver compounds almost always act to some extent on the gelatine. It must be borne in mind that all emulsions when technically "dry" contain a certain amount of water.

The action of the silver upon the gelatine depends on the composition of the emulsion with respect to the amount of soluble silver present, the percentage of such an acid as citric acid, the humidity of the air in which the paper is kept which regulates the amount of water in the gelatine film, the nature of the gelatine used in making the emulsion, the temperature to which the emulsion was heated during the time it was being made, the time taken for drying, the temperature of the drying room, and, finally, the age of the emulsion.

The correct drying of the paper is especially important. It must not be dried at anything approaching a high temperature—I believe about 80 deg. F. is right—and it must be dried very quickly. These two conditions can be brought about together by passing dried air heated to the correct temperature continuously over the paper. Dr. Backeland has suggested the refrigerating method of drying the air for this purpose.

The soluble silver of the emulsion which combines with the gelatine gives compounds, the greater part of which are soluble in "hypo" solution, and so are eliminated in fixing. I believe sometimes the whole of them are soluble, but I have never come across paper in which this has been the case to my knowledge. Normally, with the best brands of paper, and with that which I have made myself, I have found the insoluble compounds present in very small quantity; but still, whenever I have exposed a print, either toned or untoned, to an atmosphere of sulphuretted hydrogen, I have always noticed that the whites were slightly stained.

The whites of a print on "Actinos" P.O.P. are not stained at all by exposure to sulphuretted hydrogen, if the print has been properly made. These compounds, insoluble in hypo, may be "retained" silver; they are certainly closely analogous. People often talk about the permanence of "silver" prints, lumping together bromide prints, "gaslight" prints, and P.O.P. prints. Nothing could be more unjustifiable.

The degree of permanence possessed by a bromide or gaslight print, properly made, whether the image is left in its original

state or whether it be toned by a *good and sound* method, leaves practically nothing to be desired. Such prints should last more than man's three score years and ten, and no photographer can reasonably require more of his prints than this. In the case of P.O.P. things are very different. The image is always readily open to the attack of traces of sulphuretted hydrogen in the air, which, by sulphuretting the silver chloride of the lake or lakes of which the image mainly consists, will, as has been pointed out above, cause fading of that image. Except very rarely, in the case of all papers but "Actinos," there is always the danger of the whites being stained on account of the action of the soluble silver compounds of the emulsion on the gelatine. All the same, I think that if a print is made on paper of a good brand, preserved well in good condition, is finished off properly, and is then kept in a dry room, it should last for quite twenty years before showing signs of failure.

The very small traces of sulphuretted hydrogen in the air seem to act very slowly if the print is kept really dry.

I think there is no objection to the use of a "combined" bath if this be used properly. *The danger here is "retained" silver and lead.* The process must be so carried out as to avoid these. The print in every case ought to be first washed and then fixed in neutral or, better still, slightly alkaline hypo. I recommend:

Hypo .....	1½ ounces.
Sodium carbonate (cryst) .....	20 grains.
Water .....	10 ounces.

The print should then again be washed well and then put into the toning bath. This method of working will prevent the acid solution of hypo taking up too much silver.

Lead, if added to this bath, *should be added only in comparatively small quantity.* The following combined bath is suitable. Dissolve 1¼ oz. of hypo and 45 grains of alum in 6 oz. of boiling water, stirring until all has dissolved. Then allow this solution to stand till cool, and then add 4 grains of powdered lead acetate. This solution should be allowed to stand 24 hours, and is then filtered. To the filtered solution one ounce of the following gold solution,

Gold chloride .....	1 15-grain tube.
Water .....	7½ ounces.

is added, and the bath is ready for use as soon as the gold colour has disappeared.

What people have put down as the result of insufficient fixing is really "retained" silver or lead, due to using a badly made-up bath, or misusing a good one—letting it collect too much silver. There always has been, and still is, a great deal of nonsense talked about the time necessary for fixation. This is not nearly as long as many people imagine. If we use a badly made up bath, or misuse a good one, the longer we expose the prints to its action the more "retained" silver or lead we are likely to get. I think that about ½ grain of lead acetate per ounce of toning solution is about right, and should not be exceeded to any appreciable extent.

I myself always recommend the use of the thiocarbamide bath. In using this bath the following three stock solutions will be found convenient:

I. Gold chloride .....	1 15-gr. tube.
Water .....	7½ ounces.
II. Thiocarbamide .....	18 grains.
Water .....	7½ ounces.
III. Concentrated nitric acid .....	½ ounce.
Water .....	25 ounces.

The prints should be washed well before toning. They are immersed in the toning bath made up as follows:—

From 60 minims to 3 oz. of III. are taken, according to circumstances, and to this are added 60 minims of I., 60 minims of II., and then this solution is made up to 5 oz. with water. The bath should be used at a low temperature to prevent the swelling of the gelatine by the nitric acid—40 deg. Fahr. should be exceeded.

The use of ice in summer is therefore necessary. Six quarter-plate prints should be toned together in 5 oz. of the solution which then is used up, and should be thrown away. Thus gold required to tone six quarter-plate prints only works out at cost one-third of a penny. Experience alone will enable one to judge the proper end of the toning action: it is at first very easy to over-tone.

After toning has been carried out the prints are just rinsed in a dish of water for from ¼ minute to 2 minutes, according to the amount of acid used in the toning bath, and are then fixed in:

Hypo .....	1¼ ounces.
Sodium carbonate (cryst.) .....	20 grains.
Water .....	10 ounces.

There must be no washing in running water between toning and fixing. The reason why washing between toning and fixing is not take place is that, as previously stated, there always is a silver combined with the gelatine of the film and the paper. This combined silver is converted to some extent into a carbamide compound, and this compound is soon decomposed except in the presence of acid. One of the decomposition products is silver sulphide, and so we get brown stains on the print if they are washed, before being fixed, for five minutes or so in running water.

Fixation should be allowed about 5 minims, not longer, and the temperature of the fixing bath should be kept low—about 40 Fahr. After being fixed, the prints are well washed in a plain washer for about an hour, and are then complete.

Before finishing this article I should like just to touch on the question of the nature of the coloured images formed by a prolonged exposure and modified development of gelatino-chloride "gaslight" papers. These images consist of lakes formed of silver and silver chloride. I have not analysed any such lakes, but I have applied the other tests mentioned above. If any of these images are bleached and then sulphuretted the image of silver sulphide obtained is much weaker than the original. If also the silver be dissolved out of the image by ammonium persulphate or dilute nitric acid the presence of silver chloride remaining can be easily demonstrated. The images, too, attacked by sulphuretted hydrogen or a solution of a soluble sulphide, gaining slightly in density at first, but afterwards fading very much. Thus the images behave just as the lakes on plainly fixed P.O.P. does.

Since, in the consideration of silver halide lakes, the work of the late Mr. Carey Lea is of great interest and importance, readers of this article may want to renew their acquaintance with his researches. In this case they will do well to turn to the "British Journal Photographic Almanac" for 1902, pages 812-814. I may say that many—I fancy most—now deny the existence of definite sub-halides of silver, regarding the bodies stated to be such as lakes formed of metallic silver and silver halide. I personally agree with this modern view. It is very difficult to conciliate such a compound as that represented by  $\text{Ag}_2\text{Cl}$  with the notions of valency.

R. E. BLAKE SMITH, B.Sc. (Lond.)

THE SUBURBAN AND PROVINCIAL DEVELOPMENT ASSOCIATION, 29, John Street, Bedford Row, W.C., send us copies of illustrated booklets, published by themselves for the District Councils of Croydon, Ealing, Finchley, and Southgate. The booklets are copiously illus-

trated, and contain varied information regarding the districts dealt with. Those who are thinking of taking up their residence in one of the above-named localities may be glad to know that copies can be obtained free on application to the respective Town Clerks.

## SOME SECRETS OF DOG PHOTOGRAPHY.

[The fame of the firm of Thomas Fall, of Baker Street, in canine photography being recognised not only throughout the kennel world but wherever portraits of dogs appear in the illustrated papers, no little interest attaches to an article under the above title in the February issue of the "Kennel Magazine," where will be found a number of reproductions illustrating the differences between right and wrong methods in photographing dogs. These illustrations are as useful as the text of the article itself.—Eds. "B.J."]

It seems strange to talk of secrets in connection with photography when we consider that nowadays every third person we meet with has a camera, and knows all there is to know about "taking photographs"; but as there are certain features in dog photography which, though they may be well known, are not generally recognised, it is, perhaps, possible to strain a point and call them "secrets." Probably there is no other branch of photography that provides such a varied experience as dog photography. With so many different breeds, each possessing its own distinct characteristics (and every single dog its own peculiarity of temperament) which it is the object of the photographer to reproduce in some degree, it is open to question whether it is ever possible to do thorough justice to a dog in any photograph, a statement with which most owners will agree, with regard to their own dogs at any rate.

### How to Treat a Dog "Sitter."

Patience is the most important factor in the whole business, though it is needless to say a love of animals is indispensable. Without unlimited patience, both on the part of the photographer and the person who takes the dog in hand, it is quite useless to attempt to get a successful picture. Of course, dogs differ; sometimes it is possible to snap a splendid position almost immediately the dog is brought out, but very often the subject objects to standing in "perfect positions" even long enough for an exposure to be made, to say nothing of focussing; and it is only after many devices have been tried, and much patience displayed, both by the dog and his tormentors, that the weary victim is allowed to return to the kennel to make room for the next, which may prove to be as easy to "take" as its predecessor has been difficult. Too much is not to be expected of dogs; nor should their patience be tried too severely. If they can be induced to remain still for a few seconds, that is all that should be required of them.

One is often met with the remark that if the dog could only be followed with a hand camera ready focussed, and "snapped" when in a good, natural position, it would be a much easier performance. So it would, but would it give the same result? In the majority of cases the picture would be quite useless, and might even be a gross libel on the dog. Dogs have such an unhappy knack of posing in places where the background is unsuitable and the light all wrong, that it is much better to fix on a suitable spot and endeavour to bring the dog up to it. Again, it is much better to photograph on the floor, and not use a table or bench (there are exceptions, of course); dogs feel much more at their ease on the ground. The camera must be brought somewhere down to the level of the subject. Hence the only way to work a hand camera would be to follow the dog about on one's knees—a rather trying task—unless the manipulator happened to be a dwarf!

### The Importance of the Background.

Choosing the background has a lot to do with the success of the resulting picture, and due regard has to be paid to the dog's colouring, in order to make the subject stand out from, and not sink into, the surroundings. Sometimes, however, it is an advantage to make the dog's weak points (such as faulty hindquarters) tone into the background (to make their existence less noticeable) and sometimes it is advisable to emphasise the good points by making them contrast with the background. Much can be done in this way by work on the negative afterwards, but in every case the plainer the background the better. How often we see a really good position of a dog spoiled as a picture by a row of flower-beds, or by ivy leaves (which appear to be growing out of the dog's head) or by iron railings, which appear to have taken root in its back!

### Dog Portraiture Out of Doors.

Dog photography out of doors is much easier than in a studio on account of the rapid exposures that can be made, but most of the smaller breeds of dogs make much better pictures indoors where the light is under control. It is quite a fallacy to imagine that the sun is better for a photograph than shade. A strong, white light, with the sun obscured by clouds, gives the best results—more details in the shadows, more roundness to the body, and a more natural picture altogether. Harsh sunlight with heavy shadows (to say nothing of the alteration in the colours of the dog due to excessively patchy high-lights on the sleek glossy coat) gives a picture that is hardly recognisable when compared with one taken in a subdued light. Old English sheepdogs, and breeds with a similar kind of coat, can be photographed in any kind of light provided there is enough of it. It must not be imagined that because a dog appears to those standing near (possibly holding him on a lead) to be in a good position, that that position will photograph well. The photographer at the camera is the best judge, since he alone can see exactly what the lens will reproduce; and he knows that pictures that have the appearance of being "full of life" often make very disappointing photographs. "Too many cooks spoil the broth," but the dog photographer would be quite helpless without some assistance from those who know the dog best; and, doubtless, one of the great secrets of success in dog photography lies in the photographer's ability to so direct those assisting that they may control the movements of the dog, and make him stand in good positions, of his own accord, and without forcing him to do anything.

It is much better to entice a dog up a step, or to lead him round for a short run and bring him up again in the required place, than to pull him backwards and forwards on the lead, as it takes a very little to make a dog blow and pant, especially in hot weather. Touching the mouth or tongue with a damp cloth will often cause the dog to close it for a second. Sometimes it is necessary to lift a dog, so that the front legs come straighter, closer together, and more on the toes. This can be done by placing the hand under the neck and lifting, at the same time speaking to the dog in a reassuring manner—not by pulling him up by the collar. Sometimes it is impossible to get a group of dogs to keep still; this difficulty may be overcome by photographing each dog separately, and then combining them.

### Posing the Dog.

Generally speaking, it is easy enough to get a dog's attention by some slight noise, but it is one of the accomplishments of the dog photographer to be able to bark and growl like a dog, mew like a cat, scratch like a rat, imitate dogs fighting, and make other weird noises; then to notice the sound that takes the fancy, and reserve it for a really good position. The mention of the name of a rival in the kennels will often succeed when every other device has failed to attract; but sometimes this has such a disturbing effect that further operations are rendered impossible. It is as well to commence in the quietest way, as it does not take much to arouse the suspicions of some dogs; and once a dog gets suspicious and nervous it is all up with a photograph. Sometimes it is possible to rivet the dog's attention by some noise or action that the person holding the dog can slightly alter the hind legs or tail without the dog's notice; often the tail will not stay in position, and has to be held, and the hand "taken out" afterwards.

Though the secrets of dog photography are many, its disappointments are many also, but its study presents a source of inexhaustible interest, and its difficulties will probably continue to exist so long as there are dogs to photograph.

THOMAS FALL.

### THE PHOTOGRAPHIC CONVENTION. THE BRUSSELS MEETING.

THE arrangements for the meeting of the Photographic Convention of the United Kingdom in Brussels from July 6 to 11 are now far enough advanced to allow the general secretary, Mr. F. A. Bridge, to issue a preliminary programme of the week's doings. The Convention, it will be remembered, is meeting in the Belgian capital on the invitation of the Association Belge de Photographie, itself a national body of considerable influence. From its members an influential reception committee has been formed, with M. Vanderkindere, 97, Avenue Brugmann, Brussels, as secretary. Sir Cecil Hertset, President of the Convention, may also be regarded as a host in himself where the organisation of the Convention's programme is concerned. Commandant Van Bever, President of the Association Belge, and the Burgomasters of Brussels, Antwerp, and Ghent, and the President of the "Cercle Artistique" are also actively interesting themselves in the arrangements for the English visitors, and therefore it would seem as certain as anything human

The Hall of the "Cercle Artistique" where the meetings and exhibitions of the Convention are to be held.

can be that, in the words of the prospectus, "members attending this year's convention will have the advantage of visiting Belgium under exceptionally favourable conditions."

The following is an abridged synopsis of the programme for the week:—

Monday, July 6.—Morning: Reception by the Burgomaster of Brussels. Afternoon, at three o'clock: Official opening of the convention, president's address, and papers. Evening: Conversazione and exhibition of pictures, apparatus, etc.

Tuesday, July 7.—Morning: Excursion to Ghent. Evening: Annual general meeting.

Wednesday, July 8.—In and around Brussels. Afternoon, at four: The Official convention group will be taken in front of the Palais de Justice. Evening, at seven: Annual dinner.

Thursday, July 9.—Morning: Excursion to the old Abbey of Villers-la-ville. Evening: Paper and a lantern display by members of the Association Belge.

Friday, July 10.—Morning: Excursion to Antwerp. Afternoon: Reception and garden party, by the President and Lady Hertset, at the Jardin Zoologique. Evening: Papers or lecture.

Saturday, July 11.—Morning: Excursion to Malines.

We omit from this sketch of the programme the notes on the attractions of the places to be visited which appear in the official prospectus. The latter, however, can be obtained on application to Mr. F. A. Bridge, East Lodge, Dalston Lane, N.E., and will be found to contain also full particulars of the very substantial reductions, about half-fare, to be obtained by parties travelling to Brussels together.

SCOTTISH FEDERATION.—At the annual meeting of the Federation, the results of Federation competitions were announced as follows:—Portfolio—Macdougald Gold Plaque: Dr. Corbet, Barrhead, and D. Hodgeton, Brechin, a tie; Lantern Slides—Coates Challenge Trophy: Dennistown; 2, Paisley; 3, Glasgow Southern.

## Exhibitions.

### THE SCOTTISH NATIONAL SALON.

ORIGINALLY held five years ago, this exhibition has gone on increasing in quantity, quality, and popularity. When first held at Perth about four hundred prints were entered, and as it was then, and is now, confined to Scottish work, that was considered a big entry this year about 900 prints were submitted to the Board of Selection at Aberdeen. The photographic members of this Board, by the way, are all in the profession, which would seem to indicate that the latter are in the ascendancy in Scotland. Be that as it may, it is evident that the Council of the Federation are satisfied that in Messrs. Craig Annan, Crooke, and Patrick, with G. R. Gowan, R.S.W., they have men in whom they can safely put the reputation of photography in Scotland.

The Art Gallery in Aberdeen, where the Salon is held, is a magnificent building, with fine suites of rooms, and this is practically the first exhibition held in them since they became the property of the Corporation. The Lord Provost remarked that he was glad it was so, as it gave the city the opportunity of encouraging a most promising art.

The walls are the usual picture gallery crimson, but the Salon Committee covered them up half-way with neutral-tinted canvas, the projection of which from the wall at the top formed a beautiful dividing line of shadow. The effect was pleasing. The Hanging Committee tried, as far as possible, to hang each entrant's work in groups, and while this is a convenience for the visitor who wishes to study each worker's pictures as a whole, it is certainly impossible to make so congruous a wall as when the entries are treated as a whole and hung with a view to decorative effect.

It was evinced by the large and influential gatherings at the private view and opening ceremony that the citizens of Aberdeen are proud to have the Salon with them, and all credit must be given to Mr. Kay and his committee for the excellent arrangements they have made; while special mention must also be made of Mr. Bentley Philip for the exceptionally fine and complete syllabus of entertainments he has drawn up for the three weeks the Salon will be open. A detailed critique of the pictures is impossible, nor is it advisable to attempt it. Our province, then, will be better served if we devote the space available to a few notes on the professional work in the Salon.

Mr. Craig Annan (Glasgow) has the largest exhibit in the Salon proper (eleven pictures), and we would regret to omit one from the walls. They display a breadth of treatment and a full recognition of the possibilities of each subject that is inspiring. Several of the pictures are well known: "On a Dutch Shore," "A Little Princess," "A Book Plate" (which is splendidly reproduced in colotype as a frontispiece to the catalogue by Messrs. G. W. Wilson and Co., Aberdeen), "Miss Jessie M. King," etc. Of the new work the most striking is "R. B. Cunninghame Graham, Esq.," which has indelibly stamped on it the character of the man; it is more than a mere facial likeness, one feels it is the man.

Mr. William Crooke (Edinburgh) sends all portraiture. There is the famous "Henry Irving" picture; the "made" group of "Edinburgh Town Council," which gives no indication of its making; "In Silk Attire," a new work, showing a lady whose silk dress is finely rendered and contrasted with the cloth jacket: conflicting elements are absent, and the whole hangs well together.

Mr. James Patrick (Edinburgh) confines himself to those rural scenes which have won him so much fame. His principal contribution, "The First Touch of Winter" (reproduced in catalogue), is his latest interpretation of a theme he has been following out for some time, the delicate gradation of tone in snow, and its value in landscape work.

Mr. J. M. Whitehead (Aloa) is a standing testimony of the value of specialisation. The occupant of a country studio, he early specialised in flowers, and so successfully that he gained the R.P.S. Medal; then he transferred his allegiance to peaceful landscape scenes, and that at a time when we were satiated with a superfluity of wild expositions of such topics as "Day's Decline." That field he made his own and again gained the R.P.S. Medal. He is represented at the Salon by five works in his usual poetic and yet academic

anner. He has not yet learned to think shame of photography by trying to make it appear like something else.

Mr. J. B. Johnston (Edinburgh) has only three pictures, but they are outstanding works; his "Beaching the Boat" is reproduced in the catalogue, but many prefer his "After the Day's Work."

Mr. W. L. Dunn, Junr. (Aberdeen) has, as a centre-piece to his collection, which, by the way, has in it good honest studio work, a beautifully delicate little print—"Ella (Camera Sketch)." This may well give a hint to some of his brothers-in-arms of what might well prove a profitable line.

Mr. George L. A. Blair (Paisley) is at present in pursuit of the elusive light effects so frequently seen in late evening, but he has evidently studied the subject until he has reached that stage where he does not know exactly what he wants, and his pictures, though striking, seem to lack that decision that characterised his work.

Mr. Dan Dunlop (Motherwell) shows "The Old Professor" in portraiture; in outdoor work probably his best essay is "Edinburgh Castle from Greyfriars," an unusual view, but an impressive one of the castle.

Mr. John Moffat (Edinburgh) shows two portraits and a seascape; mostly in costume work of the time when "the world went very well on"; there is an air of daintiness and refinement in these pictures that is perfectly in touch with the period portrayed.

Mr. John Moffat (Edinburgh) shows two portraits and a seascape; good honest photography and the photographic basis in no way disguised.

Mr. P. D. Nairn (Stirling) is represented by two portraits, one of a wife who has seen life, one a young lass entering life; good straightforward work.

Mr. J. C. S. Mummery, President R.P.S., sends a one-man show. Mr. Armytage Sanders (London) has collected and sent natural history photographs by different specialists. Mr. Henry J. Comley (Bristol) has twenty colour photographs.

These notes are far from exhausting what might be said, but they will serve to show that as a whole the Aberdeen Scottish Salon does not fall below its predecessors.

## Patent News.

*Process patents—applications and specifications—are treated in Photo Mechanical Notes.*

The following applications for Patents have been received from January 3 to February 8:—

**LENS-CARRIER.**—No. 2,525. Method and mechanism in order to prevent the pushing in of the lens-carrier in hand cameras before the lens-panel is in the exact centre. Fabrik Photographischer Apparate auf Aktien, vormals R. Hüttig und Sohn, Camera House, Farringdon Avenue, London.

**MOUNTING.**—No. 2,538. Improved method of mounting photographs, engravings, and the like. Louis Hyde, 30, Duke Street, Chester.

**CINEMATOPHOTOS.**—No. 2,584. Process and device for the production of living pictures in relief by means of the cinematograph. Boris Weinberg, 35, Cannon Street, London.

**PHOTOGRAPHERS.**—No. 2,738. Improvements in, or connected with, photographic cameras. William Lawrence Parkinson, 15, Water Street, Liverpool.

**COLOUR PHOTOGRAPHY.**—No. 2,746. Combined dark-slide and developing dish for colour photography. Roger Barwick Hutton, Heslerton Cottage, Pitsea, Essex.

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**AUTOMATIC SHUTTER RELEASES.**—No. 1,487. 1907. The invention provides means whereby the shutter of a camera can be released after a time fixed by the operator.

One form, shown in Fig. 1, consists of a cylinder 1 and a piston 2, capable of sliding therein. The piston will ordinarily be made of fit air-tight in the cylinder by means of a cup leather 3. Attached to the piston is a piston rod 4, which will usually be tubular, the piston rod passing freely through a hole in the cylinder cover

5. A helical spring 6 is coiled round the piston rod, abutting against the cylinder cover and against the piston, so that when the piston rod is drawn out the spring will be compressed. A nozzle 7 is provided for connecting the apparatus to the pneumatic shutter of a camera by means of a rubber tube 8. Pivottally mounted on the cylinder is a trigger 9, having a long arm 10 and a short arm 11. The short arm of the trigger projects into a longitudinal slot

Fig 1

12 in the piston rod, and a spring 13 is so disposed inside the tubular piston rod that its point 13a will engage with the short arm 11 of the trigger when the piston rod is drawn out, and will hold the piston rod in its extended position so long as the trigger is not allowed to turn on its pivot, but the pressure of the helical spring tends to cause the trigger to turn and release the piston rod.

For the purpose of holding the trigger in position, a piece of fuse tape or paper 14 is pressed on to the extreme end of the long arm of the trigger and on to a point or hook 15 attached to the cylinder. The exposure is effected by lighting the fuse, which will be longer or shorter according to the time that is required to elapse before the exposure takes place. When the fuse has burned away the trigger is free to turn on its pivot, releasing the piston rod, and allowing the piston, actuated by the helical spring, to traverse the cylinder, driving before it the air contained in the

Fig 2

cylinder, and operating the pneumatic shutter to which the apparatus is connected.

Fig. 2 shows a modified form of the apparatus designed to give time exposures of graduated length. This form is intended to be used with pneumatic shutters, which are caused to open by air pressure, and to remain open until the air pressure is released. The disposition of the various parts is similar to that shown in Fig. 1, except that the spring 13, Fig. 1, is replaced by a member 16, Fig. 2, in which are formed a series of notches 17, any one of which may be caused to engage with the trigger, according to the distance to which the piston rod is drawn out. A fine hole 18 is formed in the wall of the cylinder, to allow the air to escape slowly. The pneumatic shutter being set so that it remains open as long as the air pressure is maintained, and closes when the air pressure is relieved, it is evident that the length of the exposure will vary according to the time required for the air compressed by the piston to escape through the hole 18. This time will be proportional to the volume of air compressed by the piston and the volume of compressed air can be varied by varying the distance to which the piston rod is drawn out. Thus the engagement of the trigger with each of the notches 17 will correspond to a definite length of exposure.

Fig. 3 shows another form adapted for use with shutters, which are operated mechanically by depressing a lever. Attached to the shutter 19 is the body 20 of the appliance, having two bearings 21, and slidably mounted in the bearings is a rod or plunger 22, one end of the rod being arranged to engage with the lever 23, which

operates the shutter. A collar 24 is formed on the rod, and a helical spring 25 encircles the rod, abutting against the said collar and against the bearing 21. The tendency of the spring is to cause the rod to slide in its bearings and to operate the shutter by depressing the lever 23. Attached to or forming part of the body 20 is a hook or point 26, and a second hook or point 27 is formed on the rod.

In using the appliance the hook 27 is brought close to hook 26 by sliding the rod in its bearings and compressing the spring 25,

and the rod is held in this position by passing the points 26 and 27 through a piece of fuse 28 in such a manner that the fuse binds the two hooks together. To effect the exposure the fuse is lighted, and after an interval of time, depending on its length, the fuse burns away and releases the rod 22, of which the hook 27 forms a part. The spring 25 then causes the rod to slide in its bearings and to engage with and depress the lever 23, thus operating the shutter. Edward Geisler Herbert, 89, Northern Grove, West Didsbury, Manchester.

**MERCURY-VAPOUR CYLINDER PRINTERS.**—No. 10,358. 1907. The apparatus consists of two supports, carrying a mercury-vapour light, which is started by being tilted, rockers to support the apparatus, and means for holding the apparatus in a position suiting the source of light. Thomas Thomassen Sabroe, 12, Colbjørnsensgade, Copenhagen.

**PREPARATIONS SENSITIVE TO LIGHT.**—French Patent, No. 380,502. 1907. Paper coated with gelatine, albumin, etc., is treated with a solution of molybdic acid, tungstic acid, or uranic acid, or of a salt of these containing some free acid. After exposure under a negative, the portions of the surface not reached by light are rendered insoluble by treatment with a solution of barium or aluminium acetate, the excess of the salt being removed by washing. Molybdic acid is said to give the best results with this process, the pictures obtained being blue; they can be toned, if desired, with gold or platinum. J. de Ruiter.

**HELIOGRAPHIC PRINTING PROCESS.**—French Patent, No. 381,020. 1907. Paper is coated with gum arabic and impregnated with bichromate; after exposure in sunlight beneath a design, the paper is washed, dried, coated with an alcoholic solution of a suitable colour, sandarac, resin, and shellac, and treated with dilute hydrochloric acid. A reproduction of the design in colour is said to result. L. Fiorillo.

The following complete specifications are open to public inspection before acceptance under the Patents Act, 1901:—

**PLATES.**—No. 18,860. 1907. Methods for loading and unloading photographic plates and the like in broad daylight. Mela.

**COLOUR PHOTOGRAPHY.**—No. 2,313. 1908. Three-colour reticules for colour photography. Krayn.

## New Trade Dames.

**"CHESS BRAND."**—No. 298,899. Photographic papers. The British Photo Paper Company, Ltd., Scott's Bridge Mills, Scott's Hill, Rickmansworth, Herts, photographic paper manufacturers. December 16, 1907.

**PHOTO-SECESSION.**—An exhibition of more than fifty examples of the work of Mr. George H. Seceley, of Stockbridge, Mass., is being held until February 25, in the Little Galleries of the Photo-Secession, New York, from 10 to 6 daily.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Ozobrome.

It must be well known to all who have practised ozobrome printing (writes the Rev. H. W. Dick in "The Amateur Photographer") that after the bath has been used to sensitise a certain number of plates, a certain weakening, or deterioration, or contamination of the bath leads to trouble and to the necessity of "doctoring." I knew exactly what had happened to the bath we might unfairly be able to put it right, but as a matter of fact we do not know for certain what change takes place, hence an element of uncertainty when the sensitiser has been repeatedly used, according to the directions issued so far. My change of method is so simple that I can only wonder that I did not think of it and put it in practice before. It is as follows:—Dip the tissue into clean water for ten or fifteen seconds, withdraw, drain for a moment or two, lay the tissue down on the bottom of a clean porcelain dish (inside the dish of course), pour on the centre of the tissue sufficient of the dilute sensitiser to saturate thoroughly (one drachm and a half for a half plate is about right), and for two minutes work this across and across with a flat soft brush, proceeding from this point in the ordinary way by bringing the plaster into contact with the bromide for printing. Inasmuch as one only brings into contact with each plaster sufficient of the sensitiser for that plaster, no contamination or weakening of the remainder is possible. In other words, each plaster has a fresh bath all to itself. The brush may now be rinsed in water and then vigorously shaken to discharge superfluous moisture, when it is ready to sensitise another piece.

## New Books.

**"TIME AND TANK DEVELOPMENT."**—No. 84 of "The Photo-Miniature" is devoted to this much-discussed topic, described in the second line of the text as "fool-proof." That it can justly claim to be a quite up-to-date treatise on the subject is proved by its inclusion of the article by Mr. Alexander Mackie which appeared in the pages no longer ago than December 6 last, since when the "Photo-Miniature" has been edited, printed, and sent to these shores. The writers deal with apparatus, English and American, for tank development, with recommendations for formulae and prepared developers, and with methods of adjusting the "time" method to varying conditions of temperature and negative. As tank methods are proving so economical in the hands of professional photographers, we can certainly recommend the "Miniature" as a convenient first book of reference on the subject. Our contemporary is published in the country by Messrs. Dawbarn and Ward, 6, Farringdon Avenue, London, E.C., and in America by Tennant and Ward, 287, Fourth Avenue, New York.

**"LIESEGANG'S PHOTOGRAPHISCHER ALMANACH."**—The twenty-eighth annual issue of this publication has appeared from the press of M. Eger, Leipzig, price M. 1 or M. 1-50 in cloth binding. Herr H. Spörl, the editor, has included a directory of German and Austrian photographic societies, a review of recent apparatus, and a number of contributions on more or less technical subjects. The frontispiece is a collotype portrait of Professor Hermann Krone.

**"THE AFTER-TREATMENT OF THE NEGATIVE."**—Messrs. Gautier Villars have issued, at 1f. 75c., a fifty-six page monograph by Ernest Conset on the use of intensifiers and reducers. It does more than prescribe the best formulae for these reagents, it contains a number of hints on the best methods of employing them and as to the circumstances in which they are best applied. The short manual confines itself to the measures to be taken when remedying an imperfect negative, and hence is appropriately entitled "Les Correctifs du Développement."

**RETOUCHING.**—A new edition of Mr. Arthur Whiting's altogether excellent handbook of retouching methods for amateur and professional reaches us from Dawbarn and Ward, Ltd., 6, Farringdon Avenue, London, E.C., by whom it is published at 1s. net. We are glad to find that the mark of public approval, in the shape

a call for a second edition, has been bestowed upon this eminently practical book of instruction.

**VOM NUTZLICHEN DURCHS WAHRE ZUM SCHÖNEN.**—Under this is a small monograph on carbon printing has been written and described by a German photographer, Herr A. Grienwaldt, of Bremen. It describes the writer's preferences as regards certain points in the process, and is evidently the work of one familiar with his subject.

**PHOTOGRAPHY BY FLASHLIGHT.**—The January issue of "The Photographer," No. 85, of our well-edited contemporary, will be read with interest by English photographers if only for the inscription at the head, "Edited by John A. Tennant and Thomas Bedding, R.P.S." Evidently Mr. Bedding's accession to the editorial management of the "Miniature" has meant the more regular appearance of our contemporary—a fact in itself for mutual congratulations. The present issue compresses within its covers a good deal of useful information on flashlight work.

## News and Notes.

**DR. HALL-EDWARDS**, of the Birmingham General Hospital, has for many years past been suffering from ulcers on his hands and skin, due to his constant use of X-rays. On Sunday last he had his left arm amputated, and hopes that the progress of the disease has been arrested. Dr. Hall-Edwards is at work on a book on X-ray treatment.

**GOERZ LENSES.**—We understand that it is possible that lenses, from the manufacture of the Goerz factory, may be offered, engraved "Goerz Anastigmat No. 2." Our readers who may be purchasing Goerz lenses are advised to see that they are obtained from a dealer in whom they can place reliance, and to be especially careful in purchasing any cheap second-hand Goerz lenses otherwise they may have spurious lenses foisted upon them.

**FRITH AND CO., LTD.**, write us from Reigate, Surrey:—"We receive in your 'Answers to Correspondents,' on February 14, a paragraph referring to 'Frith, Photograph Publisher, Reigate, is dead.' This in reply to your correspondent 'J. P. W. D.' We thank, however, in justice to the above-mentioned firm you should be in your next issue that although, as you put it, Frith is dead, the firm is carried on under the style of 'F. Frith and Co., Ltd.' We notice you have been good enough to do in the case of the person mentioned in the earlier portion of the paragraph."

**JOHN THOMPSON, VENTNOR.**—Miss Lilian Thompson writes us, from 9, Pier Street, Ventnor, I.W., as follows:—"I should like to correct an error in this week's issue of the 'B. J.' My father purchased this business from the late Mr. Fred Hudson more than twenty-two years ago, and has carried it on since in his own name, John Thompson." As Mr. Hudson had no son, it is strange how a misconception should have arisen."

**THE FALLOWFIELD SMOKER.**—The employees of the firm of Jonathan Fallowfield will hold their annual smoking concert at Frascati's restaurant (Banqueting Hall) on Friday, February 28, under the presidency of Mr. F. W. Hindley. Tickets, price 1s. each, may be obtained of any of the employees, or of Mr. J. C. Preece, hon. assistant sec., 146, Charing Cross Road, W.C. An advance copy of the programme, kindly sent to us by Mr. Duncan Hindley, shows that a most enjoyable evening should be spent. Ladies are specially invited, and morning dress will be worn.

**BULBECK AND CO.**, technical photographers, 158, Strand, W.C., notify us that they are now on the telephone service—No. 749 City.

**STOLEN APPARATUS.**—The City Sale and Exchange, Fleet Street, London, E.C., notify us that the following articles have been stolen on February 18 from one of their messengers: No. 33 quick-focus Tak, box form, for pictures 5½ in. by 3½ in., pencil mark inside base A/X, stamped 9797, in leather case; two Elite quarter-plate focal-length cameras, collapsible model, no slides; one marked in pencil A/M, the other marked C/O/M, Nos. 4996 and 9874; one Ross homocentric lens, Series C, in focussing mount, working at f/3, No. 10,337, number engraved on lens 67064; one 5 in. Ross homocentric lens, Series C, working at f/6.3, No. 10,338, number engraved on lens 67061, also in focussing mount; 5 by 4 Planex box camera, marked in pencil on base A/X/M, no ground glass at back, no slides; one wood camera lens panel; one Dallmeyer flange.

## New Apparatus, &c.

The Graber Automatic Bromide Exposing and Developing Machine. Made by E. Graber, 16 and 38, Newton Road, Tunbridge Wells.

We have so often insisted on the importance to the photographer of acting as his own postcard producer and publisher that we are bound to draw attention to any device which assists this desirable and usually profitable end. The Graber machine occupies a position intermediate between the hand-fed machines and the large rotary installations capable of running off the largest editions. True, the Graber is capable of large output, such as 100,000 per day, but its advantage to the local producer lies in the fact that it can equally be economically used for short runs of, say, only two or three sets of exposures.

Fig. 1.

The bromide or gaslight paper is fed off the reel and brought behind the frame of fourteen negatives, each of which is supplied with a separate lamp, adjustable to the density of the negative. This plan is preferred to the method of "equalising" the densities of the negatives in a set with oil paper, and it obviously permits of more rapid adjustment. The exposure is automatically repeated once it

Fig. 2.

has been set. The machine, as shown in Fig. 1, also allows of printing any size of negative up to 25 x 12, it occupies very little floor space (3ft. 6 in. square), and can be worked by hand or power.

Accessory to the printer is the developing machine, also the invention of Mr. Graber, and produced, in the first instance, for the Falla-Gray paper, which, as our readers may recollect, fixes in one minute and is washed free from hyposulphite in five minutes. The washing part of the installation in this case is, of course, much shorter than for other makes of paper, but the series of trays can be adjusted for the paper to be treated for any length of time in the developer, fixer, and wash-water. Moreover, one other

feature of the printer should be mentioned—namely, its facility for simultaneously applying letterpress printing to the front of the card.

We recommend all those interested in acquiring a machine, which they can install in an establishment of moderate dimensions, to apply to Mr. Graber for prices and particulars of the machine, which certainly, in our judgment, is a most efficient and well designed piece of apparatus.

## New Materials, &c.

**"GREUZE" MULTIPLE MOUNTS.**—Messrs. W. Butcher and Sons send us samples of mounts which they have issued to meet the beginner in multiple mounting half-way. Multiple mounting must always be quite individual, and we cannot imagine Mr. Evans abandoning his practice of building up the mount behind his print to employ a ready-made mount of several tints. However, as an introduction to the beginner in the use of several tinted mounting papers, the "Greuze" series is convenient and inexpensive. Twelve mounts, for quarter-plate prints, each with two pasted-on tints, cost 1s. An improvement, we think, from the pictorial standpoint, would be the placing of the pasted-on tints slightly above the geometrical centre, so as to conform with the classic rule of an equal space above and on either side of the print and a greater space below.

**FLAT POSTCARDS.**—A sample of a new preparation for producing flatness of postcards has been sent to us by the maker, Mr. A. W. Bowen, of 193, High Street, Watford, by whom it is supplied at 1s. 9d. per 100z. bottle, post free. The material consists of a pale coloured weak jelly, which is made ready for use by placing some lumps of it in a jar standing in hot water. The prints, as they come from the wash water, are laid, picture side down, on glass, and the address sides painted over with the warm fluid preparation. On allowing them to dry spontaneously, the cards remain practically as flat as can be desired, and after a little pressure will retain their flatness even if stored in the heat.

**LILLYWHITE PAPERS,** gaslight, bromide, P.O.P., and self-toning are now used as "semi-matt," in addition to the matt and glossy brands, which have already been accorded a considerable measure of favour.

## CATALOGUES AND TRADE NOTICES.

**BARGAINS AT HOUGHTONS.**—Messrs. Houghtons Ltd. have in the press a list of bargains in all the lines which they are not cataloguing in their new general list. It will be ready by the time these lines appear, and we may therefore advise immediate application for it. The goods may be ordered through a local dealer.

**NEW PHOTOGRAPHIC LENSES.**—Messrs. A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, London, W.C., have just issued a new list of their latest novelties in lenses and other apparatus. Though the list runs to 48 pages, practically every item is of recent introduction. Special mention should be made of the Pulligny anachromatic lens, which is supplied by Messrs. Staley, and instructions for the use of which appear in the list; of the Staley-Wheeler high-power telephoto lens, the Staley-Wheeler folding lens shade, reflex and folding cameras. The lens is certainly one to be acquired, and is sent by Messrs. Staley on receipt of one penny stamp.

**"A GUIDE TO PHOTOGRAPHIC PRINTING."**—A 32-page booklet has been issued by Messrs. Thomas Illingworth and Co., and in its attractive cover should be certain of creating interest on the dealers' counters, for which purpose a supply can be obtained free. The booklet describes the working of the firm's bromide, gaslight, and self-toning papers, gives a good many useful hints, and is a publication of interest to both the professional and amateur worker. Single copies are sent free on application to Messrs. Illingworth, at Willesden Junction, N.W.

**PROFESSIONAL REQUISITES.**—Messrs. Sichel and Co., 52, Bunhill Row, announce they have now thoroughly rearranged their show-rooms, and are showing an exceptionally fine range of accessories and Rocco and other frames.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, FEBRUARY 21.

Sutton Photographic Club. "Warm Tones on Bromide Paper."  
Tunbridge Wells Amateur Photographic Association. "Carbography." Rotary  
Photographic Company.  
Cardiff Photographic Society. "Switzerland Revisited." Rev. J. E. Dawson.

MONDAY, FEBRUARY 24.

Scarborough and District Photographic Society. "Swiss Snaps." E. L. Davis.  
Southampton Camera Club. "By Battlement, Wall and Tower." James Shaw.  
Bradford Photographic Society. "Enlarged Negatives." Rotary Photographic

### ROYAL PHOTOGRAPHIC SOCIETY

MEETING held Tuesday, February 18, the president (Mr. J. C. S. Mummery) in the chair.

A lecture was delivered by Mr. A. H. Blake, M.A., on "London in the Eighteenth Century." The lecturer illustrated a fascinating discourse with photographs taken by himself of survivals of eighteenth-century architecture in London, and with a number of reproductions of Hogarth's sketches of the life of the period. The lecture, which was in Mr. Blake's accustomed pleasant conversational style, showed the many interesting bits to be found in London by those who will take the trouble to acquaint themselves with the history of the past, as they can do, for example, in the writings of the late Sir Walter Besant. A hearty vote of thanks to the lecturer concluded the proceedings.

CENTRAL TECHNICAL COLLEGE PHOTOGRAPHIC SOCIETY.—Meeting held February 12. Prof. Henrici occupied the chair. Mr. N. M. Clougher related some very interesting experiences with a cinematograph in Canada. Mr. Clougher first showed one of his first attempts, taken from a tram car on the Thames Embankment and Westminster Bridge. After various scenes on board ship, films of the following were shown:—"Tram Car Ride in Toronto," "Log-rolling Contests," "Lumbering at Latchford," "Canal Lift-lock at Ottawa," "Fire Drill in a School," and "A Fire Station Turn out." In concluding, the lecturer acknowledged his thanks to Messrs. Hepworth for the machine used during the evening.

LONDON PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—At the meeting held February 13, 1908, Mr. A. Haddon being in the chair, Mr. A. E.

th lectured upon "A two-eyed lens." This was, he said, an  
ary lens by the aid of which either single pictures or double  
ures could be taken at will, and for taking stereoscopic pictures  
ing was moved or altered except the diaphragm. The stops  
at be of any shape, either round or square. The lens used  
demonstration purposes was a Fallowfield portrait; for stereo  
k he often used a Zeiss Unar; in fact, he said, any lens of suffi-  
diameter might be used. The lecturer first focussed upon the  
t the filament of an ordinary electric incandescent lamp. On  
ing a cardboard stop in front close to the lens, with two holes  
t, thus — ○ ○ — it was shown at once that two images  
e there, and both quite sharp. Mr. Smith went further than  
and by increasing the number of holes to 5, 9, and 50, showed  
the lens gave a distinct image for each hole added. If one  
the two-hole stop and exposed a plate through one hole only,  
then exposed another plate through the other hole, the two  
tives would be found to give perfect stereoscopic views, examples  
which were passed round.

question as to the proper separation for a pair of lens of 2½ in.  
is opened up an animated discussion, and Mr. Smith showed a  
v of the dome of St. Paul's, taken at a distance of 2,000 feet, in  
ph the separation was 180 feet. The separation should be in pro-  
portion to the distance of the nearest object, and for interior work  
best separation would be from 4 to 4½ inches.

OUTHAMPTON CAMERA CLUB:—"A Few Recollections of Bruges"  
is the title of a successful competitive lecture given by Mr.  
E. Parsons on Monday last. A two-days' sojourn in this "old  
of Flanders" was described, and well illustrated with a series  
slides depicting various quaint street scenes and typical figure  
ies. Mr. A. R. Bacchus contributed an interesting discourse,  
led "Our Reptiles and Batrachians." A humorous account of our  
in Cornwall by Mr. F. Russell was much appreciated, and  
evening terminated with a short account of Netley Abbey,  
ribing its historical connections and architectural beauty, by  
R. Robinson.

## Commercial & Legal Intelligence.

ANVASSER SENTENCED.—George Wood, photographer, Galashiels,  
ded guilty in the Jedburgh Police Court, of having, in various  
es in Roxburghshire, received money in payment of photographs  
ook, or pretended to take, and did not forward, or intend to for-  
d, to the parties. The total amount was £3 8s., and thirty-nine  
s were scheduled. In one instance he pretended to take the photo-  
hs of twelve persons with two plates. Sheriff Baillie sent him to  
on for six weeks.

DISSOLUTION OF PARTNERSHIP.—The partnership between George  
ard Crooks and Harry Martin Sharp, cinematograph film manu-  
urers, of Mitcham, Surrey, has been dissolved by mutual consent,  
all debts due and owing will be received and paid by G. H.  
oks.

DETENTION OF A LETTER.—Before his Honour Judge Bompas, K.C.,  
he Bradford County Court last week, an action was brought by  
Emil Scholl, photographer, of Briggate, Leeds, against Joseph  
mont, photographer, Bond Street, Leeds, and Bradford, for £5  
ages for the detention of a letter. Mr. J. W. Perkins appeared  
behalf of the plaintiff, and Mr. W. W. Holmes represented the  
ndant.

r, Perkins stated, in opening the case, that on October 12 a  
r was addressed to Mr. Scholl, care of Mr. Rosemont, Bond Street,  
s, by a former employee of the defendant. The plaintiff, who  
an operator for the defendant at his Bradford studio, was in the  
it of calling at the Leeds studio, and on October 14 he saw the  
ndant, who said nothing about having received the letter. From  
ain remarks which Mr. Rosemont afterwards dropped, the  
ntiff suspected that a letter belonging to him had been opened  
the defendant. In consequence, the plaintiff gave the defendant  
ce of his intention to leave his employment. No serious damage,  
aps, had been sustained, but a claim was made for £5 for what  
a wrongful and indeed a criminal offence.

is Honour, in giving judgment on Tuesday last, said he was  
y to admit the defendant's statement that he opened the letter

without noticing the address, but he could not accept the statement  
that he read it because he thought it might relate to his business.  
There were two causes of action in the case. First, the defendant  
was guilty of trespass in opening the letter, and that, even if he did  
so supposing at the time it was his own. He thought that he ought  
in this case to give exemplary damages to secure the privacy of  
letters, and he fixed them at £5.

But besides opening and reading the letter, the defendant put it  
in his drawer, and took no steps to deliver it to the plaintiff. Con-  
sequently, he must consider what were the duties of a person who  
took in a letter addressed to his care. As the defendant put the  
letter in his own drawer with the intention of converting it to his  
own use and only subsequently decided to return it to the plaintiff,  
he was liable in trover, and although this was of less importance to  
the plaintiff, who had already seen the manageress, he thought it  
was a wrong for which he ought to give some damages, and he would  
give judgment for £3 under that head. He gave judgment, there-  
fore, for £8, and, notwithstanding that it had been necessary to  
alter the particulars, he thought he ought, under the special  
circumstances, to give the full costs, and he put them on "B"  
scale, as he thought the action was one of public interest, and  
involved difficult questions of law.

## Correspondence.

\*• *We do not undertake responsibility for the opinions expressed by  
our correspondents.*

\*• *Correspondents should never write on both sides of the paper.  
No notice is taken of communications unless the names and  
addresses of the writers are given.*

### PHOTOGRAPHIC EXHIBITS AT THE FRANCO-BRITISH EXHIBITION.

To the Editors.

Gentlemen,—Would you be so good as to help me to draw the  
attention of your readers to the Scientific Section of the Franco-  
British Exhibition which is to be opened next May at Shepherd's  
Bush? Sir Norman Lockyer, the Chairman of the Committee of  
this section, has devoted himself energetically to the work, and  
the result promises to be that we shall have a really representative  
collection of scientific apparatus. The photographic portion of it,  
however, will not, I fear, compare favourably with the rest. We  
have a large number of illustrations of the applications of photo-  
graphy to scientific purposes, but these will, of course, be distrib-  
uted among the various classes to which they properly belong—  
astronomy, biology, etc.

Exhibits illustrating the progress of photography itself are for  
the most part lacking. I take it that this is due mainly to the  
fact that photographic research is now for the most part of a  
commercial character. A great deal of investigation is going on,  
but it is mainly in the laboratories attached to photographic manu-  
factories. We get the results in the form of improved photographic  
materials, but of necessity the manner in which these results are  
obtained is not divulged. If, then, any of your readers are willing  
to lend any illustrations of the progress of photographic research  
in France or in England during recent years, their assistance would  
be cordially welcomed by the Committee.

There are no charges in connection with the Scientific Section.  
Intending exhibitors should communicate with Sir Alexander Pedler,  
C.I.E., F.R.S., the Honorary Secretary of the Science Committee,  
at the offices of the Exhibition, 56, Victoria Street, S.W. As the  
time is now getting short, it would be well if they would communi-  
cate at once.—Yours faithfully,

H. T. Wood

Royal Society of Arts,

John Street, Adelphi, W.C.

February 12, 1908.

### A SIMPLIFIED METHOD OF DEVELOPING AUTOCHROMES.

To the Editors.

Gentlemen,—You were good enough to publish my letter on this  
subject and to comment on my specimens. You are quite right in  
saying that the slide I sent to you was too dense, although it

appears more dense than it really is, because the background was a black cloth. It was one of the first I did by the method I described, and since then I have made many very much better. I find that the control which is possible is very great, and to show you how great it is, the enclosed Autochrome (which is broken, but will serve the purpose) was developed for sixteen minutes in rodinal 1-10. During the whole of this time it was exposed to a light sufficient to clearly define the outline of the plate in the dish, and was frequently examined by red light. If the finished result be required very transparent, the first development must be carried on longer. If, after reversal, it appears that too much density will result, I expose to light, place in a weak rodinal solution until a slight fog appears all over, and replace in the reversing solution, thus reducing. The redeveloped plate may be placed in a 5 per cent. solution of ammonium persulphate, followed by 10 per cent. solution of sodium sulphite, to accomplish the same result. Slight fogging during development has no prejudicial result, merely tending to thinness in the finished slide.

It would appear that rodinal has the effect of eating away the image it forms, for I find that after a rather prolonged development the true colours are all shown without the necessity of the reversing solution, the parts which appear the darker by reflected light showing transparent by transmitted light. Personally, I have done with ammonia, pyro, and nitrate of silver, for even the fascinations of the Autochrome process are not sufficient to compensate for the appearance of one's hands after immersion in these chemicals.

I am strongly of opinion that success with Autochromes depends entirely on the first development, and that the plate should be carefully watched. I have obtained results almost indistinguishable with from one minute up to sixteen minutes in the developer.—Yours, etc.,

WILLIAM E. CLIFTON.

St. Peters Chambers, Nottingham,  
February 15, 1908.

[The Autochromes sent by our correspondent are as excellent examples of the process as could be wished.—Eds. "B.J."]

#### PHOTOGRAPHERS AS PROFESSIONAL MEN.

To the Editors.

Gentlemen,—“The status of professional photographers.” Is it completely commercialised away?

An every-day occurrence frequently illustrates conditions, and answers such questions often better than pages of verbosity. My studios were visited recently by a lady to make an appointment and arrange terms for photographing her on horseback, in our public park.

The time was fixed and terms arranged, apparently satisfactory to my client, and fairly remunerative to myself, but in a quarter of an hour or so she returned and greeted me thus: “Oh, Mr. Barry, would it not be cheaper if I was merely snapshotted?” I fairly gasped, and on recovery began to explain—But I have written enough. I have touched the button, and my readers' thoughts must do the rest. Oh, daily reflections! How our art is belittled in the esteem of the public!—Yours faithfully,

W. BARRY.

Hull,

February 17, 1908.

P.S.—I further cogitate. Is the price to be charged in accordance with the speed of the shutter?—W. B.

To the Editors.

Gentlemen,—I have for some time past been reading in your columns the correspondence *re* “Photographers as Professional Men,” but cannot for the life of me understand as to the origin of the controversy raised. Do the public as a body and by common consent ignore to recognise a photographer as a professional man, or is it a hue-and-cry raised by a certain class of photographers who have neither merit in themselves nor can endure keen competition?

I am strongly of opinion that a photographer who has justly and meritoriously placed himself in a sphere whence he could command respect and admiration will not for a moment condescend to enter into such a controversy.

Let each who desires to enter into this blessed arena of social

status which an honest, deserving, and talented artist has power to build for himself after years of toil and patience, strive to raise himself to that standard of efficiency and moral conduct, and the public will not grudge to look upon the whole class of photographers as professionals deserving of all respect and esteem, if it has reason to look upon only a limited number in that light.

It is impossible to introduce hard and fast rules to regulate the onward or downward march of those engaged in this profession, and consequently the whole question must be left to the good will and common sense of the enlightened public, who have heart wide enough and understanding sufficient to extend praise and esteem where either or both are due.

The respect, in my opinion, does not lie in simply belonging to a profession, but in doing credit to it, and the public is always the best judge of our performances.

It is unwise, therefore, to force the question upon their notice by complaining of their (photographers') social status and the like, at the least said on the subject the better for all concerned.

It is absurd to talk about improving the status of this profession by introducing examinations. Are there not let loose in the world doctors good, bad, and indifferent, and did they not one and all strive to secure diplomas? If to pass examinations was only a sure method of “weeding out the unfit,” then the least said of such fallacy the better.

The “unfit,” in my opinion (if I may be allowed the expression “weeds himself out”—the very word suggests it; and consequently he is the least likely to cause apprehensions in the minds of those with such good taste pose themselves as “fit” for the profession.

Fearing I might transgress the limit allowed for such a correspondence, I conclude, and remain, yours, etc.,

M. B. MISTRY.  
3, Glazbury Road, West Kensington, W.,  
February 14, 1908.

To the Editors.

Gentlemen,—It is not my intention to discuss the question of professional photography any further, as my views upon the subject were fully given in my original letter. I feel compelled, however, to indulge upon your space once more to put the gentleman who styles himself unfit right upon one point.

I must ask him to once more read the letter written by “Status” and after carefully doing so, again refer to my reply to it. He will then find his chief cause of complaint against me—i.e., the “unfit”—was not mine. I asked, and still want to know, who are to be classified under such a heading, my contention being that each worker makes his own reward and position, whether it be solely for “bread and butter and motor-cars,” or coupled with the satisfaction of executing artistic work, which gives pleasure both to the customer and photographer, who, I feel sure, “the unfitted one” will allow me to term an artist.—Yours, etc.,

W. R. GOODYER.  
33, High Street, Bognor,  
February 15, 1908.

ANALYSIS OF SODIUM SULPHITES.—It is commonly supposed by photographers that this substance is very liable to deterioration and that special care should be taken as to its purchase and storage. With the object of ascertaining how far this supposition is justified by fact I have recently (says a writer in the “Pharmaceutical Journal”) determined volumetrically three samples of sulphite from ordinary stock—viz., the commercial, the recrystallised, and the anhydrous salts. In the first-named 94.5 per cent. of pure sulphite was indicated, the recrystallised showed 96.25 per cent., and the anhydrous 84 per cent. From this it would appear that for photographic purposes it is not necessary to use the recrystallised sulphite, which costs double the price of the commercial salt, a good sample of which should meet all requirements. The anhydrous salt compares unfavourably with the crystalline, probably on account of its not being absolutely free from water. This I have not, however, proved; but it would appear advisable not to reckon the anhydrous sulphite as being of twice the value of the crystalline, as it should be theoretically, but to take from 55 to 60 parts of the former as equivalent to 100 of the latter. [Surely twice is near enough.—Eds. “B.J.”]

## Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

Carver, 6, Church Street, Maestog. Two Photographs of the Rev. Canon Maurice Kelly.

Waltenberg, 419, Bethnal Green Road, London, N.E. Photograph of William Kettle, Junior.

Hawley, Mayfield, Blyth Bridge, Stoke-on-Trent. Photograph entitled, "A Freak of Nature."

Elliott, 31, Wellington Road, Bearwood Road, Birmingham. Four Photographs of Combined Photographs and Drawings of Girl's Head.

Milne, 65, Cumberland Street, Edinburgh. Photograph of the Shop Front of J. H. Davidson & Co., Grocers, 14, Graham Street, Leith.

W. Britton, 50, Green Lanes, Stoke Newington, London, N. Two Photographs of the Mayor of Hornsey. Photograph of the Mayors of Hornsey.

TERIST.—Wellington and Ward, Elstree, Herts.

B. MISTRY.—The best publication we can suggest is the "Bulletin of Photography," 606-608, Sansom Street, Philadelphia, U.S.A.

F. R. (Ilford).—It is our custom to look after these matters ourselves in the cases where we wish to do so.

ENLARGING.—1. Is it necessary to have a condenser for daylight enlarging? 2. What lens do you recommend for enlarging? 3. Would you employ for a half-plate negative a condenser the same size, viz., 6½ in., say, to enlarge it to 24 x 18 in.?—W. B.

1. No. 2. The lens with which a negative is taken will usually do well for enlarging. 3. A half-plate negative requires a condenser at least 8½ in.

MARKINGS ON NEGATIVES.—Can you explain the cause of the white streaks in the sky arising from the top of the buildings in one, and telegraph post in the other? These pictures are taken on "Imperial" special rapid backed plates, and are developed with pyro and soda diluted developer in a "Rystos" tank.—F. H. W.

The phenomenon presented by your photographs is one of a fairly common and very interesting type. It is partly due to development in a perfectly still developer, and would not have been manifested in streaks if the developer had been kept in motion. In a flat dish it would probably have taken the simple form of a white outline round all dark objects. You have the outline, but owing to the vertical position of the plates and stillness of the developer streaks have also formed. Movement would have prevented the formation of such obvious streaks, but we doubt if the white outline can be avoided altogether, though a good deal probably depends on the developer used. If you carefully examine all dark objects where they are seen against a light half-tone, you will detect a pure white border surrounding the dark. In the negative there should be a corresponding dark border. The explanation is as follows: Where the developer is at work on a half-tone it is partly oxidised or exhausted, but the developer over a dark shadow is unaffected. If the developer is quite still the exhausted portion is replenished slowly from the bulk of the solution, but more rapidly where it adjoins developer that is doing no work at all. Therefore development proceeds more rapidly just on the immediate margins of the deep shadow. In your street scene such white borders are quite easily apparent, and in the other view the piers of the bridge show them very plainly. The streaks are evidently caused in the tank by the fresh developer from the shadows slowly diffusing in a straight current across the half-tone. We assume that the plates were

developed in the tank with their greatest length horizontal, and with the image inverted. We should be greatly obliged if you would inform us whether this was the case or not, as the phenomenon is one interesting to study.

MASTER AND APPRENTICE.—I should be glad if you would kindly inform me, through the medium of your paper, whether I could legally make any deductions from wages of an apprentice who makes it a practice of coming late to business in the morning.—APPRENTICE.

We are not sure that you can legally make deductions from the apprentice's wages for coming late to business. But if he misbehaves himself or neglects his duties you can bring him before a magistrate, who has full power to deal with such cases.

ENLARGED NEGATIVES DIRECT.—Can you tell me if there is any practical and sure method of making enlarged negatives direct? I have tried some methods which have been published, but failed entirely. Information will be thankfully received by an old reader.—J. GRIFFIN.

A pity you do not tell us which methods have failed you. Have you tried enlarging on a plate of "ordinary" speed and reversing by the persulphate method on page 838 of the "Almanac"?

E. J. BOWLES.—The Page-Croft Paper Company, Cooksey Road, Birmingham.

MEMO.—(1) MESSRS. Siebel and Co., 52, Bunhill Row, E.C., and the Tress Company, 4, Rathbone Place, W., both supply a studio instrument. (2) For cabinet portraiture the lens should be at least 10 inches; all the better if 12 or 14. (3) The references to Simplex were not preserved, consequently we cannot give them to you.

READER.—The "Videx" and "Soho" both have this movement. If you apply to Messrs. Marion and Co., Soho Square, W., and Adams and Co., 26, Charing Cross Road, W.C., you can obtain illustrated prospectuses.

ONE SOLUTION DEVELOPER.—(1) Can you give a one solution developer, metol hydroquinone formula, which will keep well for a considerable time? (2) I intend purchasing a ½-plate reflex camera, but am a little undecided what make, as they are so widely different in price. Several makes, such as Staley, Lancaster, Watson's, etc., about £12, and Adams' and Newman and Guardia, etc., about £40. What is the difference in the cameras, etc.? Can you advise?—N. O. D.

(1) The Velox metol-quinol formula ("Almanac," p. 854), if made up with the best chemicals, will keep for months in corked bottles. (2) The best advice we can give you now is that you look up our issue of June 14 last, in which you will find a review of practically every reflex on the market. If there are then any special points on which we can advise you we will be glad to do so. The higher-priced reflexes differ chiefly in the conveniences provided for rapid alteration of shutter speed, range of rise of front, etc. It is a question of what you want. We would suggest, too, that you consult the reviews and advertisements of reflex cameras in the "Almanac."

COPYRIGHT.—About thirty years ago a member of the firm we now represent obtained permission to photograph and publish an article of considerable historical interest, the owner bringing the subject into the studio and waiting while several negatives were made of it. A few years ago we published the same in postcard form. Can the present owner, the third in succession, prohibit us from publishing the same? We possess no written permit to publish, but the facts are as stated, and a member of the firm was present when permission was granted and the photographs made.—MCISLE.

You have every right to publish the photograph, unless it can be shown that your firm was paid in the first instance for taking the photograph.

F. S. C. (Bordeaux).—No such rules are published. Your best plan would be to address yourself to one of the English manufacturers, such as Wellington and Ward, or Ilford, Ltd.

K. ROBSON.—You had better address your query to the "English Mechanic," Clement's Inn, London, W.C. The subject is not in

our province at all. Your letter suggests that you are confusing block tin with pure tin. Block tin is only an extra quality of tin plate, and it can be worked just like ordinary tin plate.

**SIMPLEX.**—Practically any of the plates you name are suitable. They are all of the highest speed. We should say there is not much difference between them.

**ENLARGING QUERIES.**—(3) I have recently started to do my bromide enlarging with an enlarger, incandescent gas for the light, but I find that the results are very harsh and contrasty, especially as I have been used to working with a daylight enlarger. I use metol hydroquinone developer, 40 drops of 10 per cent. potass bromide solution to the 40 ounces. (4) Could you suggest a way to get softer results, either by using another developer or by altering the light? Also the name of a good book on bromide printing and enlarging?—H. M.

(1a) Yes, quite long enough. (1b) Not much to choose between the two as regards weight. (1c) For general usefulness outside of the studio we should certainly prefer A to B. (2) Quite the same as regards permanence; perhaps a little heavier in appearance, but with the rich quality of the print made in the ordinary way. (3) You are probably under-exposing, although a comparatively weak light tends to give stronger results. We recommend you to pick a rapid, soft-working bromide paper and use amidol as developer. (4) One of the spirit incandescent lights, such as the "Sol," would help you. About the best book we can suggest for your apparent difficulties is "Enlargements: Their Production and Finish," by G. Rodwell Smith (Hazell, Watson and Viney, ls.) (5) Certainly it may be used, but there is a certain amount of smoke, and a number of successive exposures could not be made without well ventilating the studio.

**POSTCARDS TO CUSTOMER'S ORDER.**—A lady customer has given me two photographs to copy her some postcards from. They are of her husband, who was a local celebrity and has just died. She tells me that she paid for the sitting in each case. Besides the order she has given me, she desires me to supply the shops in the district for sale. The photographer who took the originals has "copyright" printed on front of both mounts. Will you kindly tell me in next issue whether I can legally supply shops or not, now that I have her permission?—ANXIOUS.

If the photographer is actually the owner of copyright, the lady's permission will not indemnify you from the consequences of infringement. Surely you can judge for yourself whether she is the sort of person a photographer would photograph gratuitously in order to secure the ownership of the copyright, or, better, you can ask her to produce the photographer's receipt for the money paid to him for taking the photograph.

**EMULSION UTENSIL.**—We have just made a small press for experimental work, to break up emulsion ready to be washed. We have made the cylinder of copper, and the bottom is made of solid gun-metal perforated with  $\frac{1}{8}$  in. holes. The ram used to force the emulsion through is made of vulcanite. The whole operation of putting through the emulsion does not take more than five minutes. The formula used is a simple chloride bromide of silver emulsion, and no acids whatever used in its make. The chief point we want to know is, will these metals used in making the press affect the emulsion while it comes in contact with them? We take it if the press was to be used for fast plate emulsions it would be best to have it silvered.—S. J.

It is absolutely necessary to silver the emulsion press, as copper will certainly before long produce verdigris and attack the emulsion. The effect of not silvering will be to produce scum marks and streaks on the plates when coated.

**COLONIAL.**—1. The general commercial prosperity in the Argentine is very good now and improving. 2. Better try a daily journal in Buenos Aires, although positions of any importance are filled through shipping agents in London. 3. Operator and retoucher. 4. We refer you to Thomas Cook and Son. 5. We know of none in particular.

**SHAVIAN, W. G. WOOD, AND OTHERS.**—In our next.

**COLONY.**—1. Prospects are generally good, but those going out will probably have to rough it. 2. Yes; English and American styles are used. 3. We should say it would certainly be better to buy here.

**R. W.—Griffiths' Steam Works, Eyre Street Hill, Clerkenwell, E.C..**

**E. SHIVAS.**—1. We think you will find sufficient information for your purpose in the editorial article in the "B.J. Almanac," 1908, and in the abstracts from Dr. Mees' lecture at the Society of Arts which we published on January 17 and February 7 in the "B.J." The full text was published in the "Journal of the Royal Society of Arts" for January 18. 2. If an Autochrome is well dried and varnished with celluloid it will stand about half a minute's exposure in the lantern without any risk, but for an exposure of several minutes we should advise the use of a water trough between condenser and slide, especially if a powerful mixed jet is in use.

**EDWIN HADLEY.**—1. E. W. Foxlee, 22, Goldsmith Road, Acton, W. 2. Glooe metal polish, 2d. tin; terebine, 2oz.; salad oil, 2oz. The ingredients are to be well mixed and strained through fine muslin two or three times to remove any coarse particles.

**WAGES DISPUTED.**—At Christmas time I closed on Christmas day and New Year's day (it being the days generally recognised through the town), and had a notice to that effect posted in my windows, but one of my assistants did not turn up on Boxing Day. I called to know the cause, and the mother said her daughter thought she ought to have Boxing Day, but she would send her to business at one o'clock. To this I agreed. The assistant turns up at two o'clock, and flatly says that she has arranged to meet a friend, and cannot stop to work, and went away again. Next morning she turns up as usual, but I sent her home again, with the understanding that she had finished. Now this mother is suing me for a fortnight's wages. Can they make my pay?—E. P.

Yes; certainly they can. The girl was perfectly within her rights in acting as she did. Christmas Day and Boxing Day are both statutory holidays in England, and all employees are entitled to them without any deductions whatever from their wages. The girl must be paid for the Christmas week, and a week's wages in lieu of a week's notice.

**R. WALLIS.**—A "supplementary" lens of a single glass will affect the definition of a good lens. A proper lens consists of a cemented pair of glasses. You had best apply to Messrs. Sichel or Messrs. Griffin, who make a specialty of these lenses.

**LENS QUERY.**—I have offered to me a large portrait lens bearing the name of "Jamin, Paris." It is about 5 in. in diameter, and the front lens is somewhat smaller than the back. Its mount is of a different shape from that of English lenses. Will you please tell me if the lens is a good one, and what size picture it will take? I can buy the lens for about £6 or £7.—T. WILLS.

The lens must be a very old one—possibly fifty years. Of course, we cannot say whether it is a good one or not without testing it, but we may tell you that Jamin's lenses were in good repute about the time this one was made, and the firm made a good number of large lenses in its time. As you do not say the focal length of the instrument we can give no definite idea as to the size plate it will cover, but from your description we should think it will cover 15 x 12. The price asked for the lens is rather more than its present market value.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

th of Mr. Horsley Hinton.—It is with very great regret that  
 announce the death of Mr. A. Horsley Hinton on Tuesday last,  
 short illness. A portrait and obituary notice of Mr. Hinton  
 on page 160.

Benjamin Stone, in presiding at the annual general meeting  
 National Record Association, drew attention to some of the  
 influences in modern photography. The report of the  
 A. Council is given on page 159.

Birmingham Society has held a successful exhibition. A  
 d review appears on page 161.

erman worker has recommended two alternative methods in  
 g plates for orthochromatic sensitiveness with simultaneous  
 drying. (P. 154.)

a recent meeting of a German society an indicator for the  
 tion of double exposures was described. (P. 158.)

e facts to be borne in mind in calculating the exposure of  
 ements are mentioned on page 155.

e notes on the purity of soda sulphite in reference to some  
 y published figures appear on page 154.

article on modifications of the method of testing the speed  
 tters recommended not long ago by Mr. Arthur Payne is  
 ted from a German contemporary. (P. 156.)

e further work has recently been done on the cause of the  
 ed Moser's images. (P. 154.)

urther patent for agar-agar paper has been taken out by  
 V. F. Cooper. (P. 163.)

ox cameras, a new printing process, and a method of finding  
 st time for the photography of a given subject are among  
 patents of the week. (P. 164.)

urther reference to the occurrence of white outlines round  
 objects in negatives developed in a tank, we publish a short  
 al, which gives some explanation of the phenomenon, although  
 gested conditions are not invariably the cause of the defect.  
 .)

hide toning is the subject of a long letter from Mr. R. E.  
 Smith which appears with other correspondence on page 169.

## EX CATHEDRA.

### Drying Negatives with Spirit.

In reference to our previous note on  
 this subject, our confrère, Herr Wolf  
 Czapek, points out that Dr. Lüppo-  
 Cramer, on page 73 of the "Photographische Rundschau,"  
 1907, has explained the milky appearance sometimes pro-  
 duced. Dr. Lüppo-Cramer stated that while the honey-  
 comb-like structure of gelatine cannot be detected under  
 normal conditions, yet it appears if the gelatine is coagu-  
 lated by alcohol, owing to the difference that then exists  
 between the refractive power of the walls of the cellulose  
 and their contents. On re-soaking the gelatine in water  
 the difference is destroyed, and the structure disappears.  
 This explanation is practically the same as that put for-  
 ward by Mr. F. F. Renwick in the letter published in our  
 issue of January 17, on page 53, and it certainly seems a  
 very probable one. Mr. Renwick suggested that the effect  
 could be obviated by not pushing the spirit-drying to the  
 limit. This is in accord with our own experience, for we  
 never meet with any trouble if the negative is simply  
 soaked in the spirit for a few minutes and then set up to  
 dry naturally. The trouble arises when several spirit  
 baths are employed in succession to extract as much of  
 the water as possible, and the drying is completed by heat.  
 If only one bath is employed it is unsafe to apply heat, as  
 the gelatine still contains sufficient water to render it  
 soluble; a whirler is, however, a very good and safe sub-  
 stitute for heat. In practice we find that rectified spirit,  
 "dried" with potassium carbonate can be used with safety,  
 if not applied more than once. It is expensive at the  
 start, but it can be used over and over again if a little  
 potash carbonate is kept in the bottle. Methylated spirit  
 of good quality can also be used, but there is always the  
 risk of trouble if the negative is subsequently submitted to  
 any chemical treatment.

\* \* \*

### Pre-Daguerrean

A curious note forms the concluding para-  
 graph in a recent article by Professor  
 von Weissenbach, of Leipsic. It is to the effect that the  
 writer has obtained from Professor Sulsén, of Dresden,  
 three prints (on salted paper) in order to prove that the  
 art of recording by the agency of light was understood  
 in Dresden nine years before Daguerre. We cannot help  
 wondering to whom Professor von Weissenbach thus  
 alludes in ascribing the authorship of a method of photo-  
 graphy comparable with that of Daguerre. The use of  
 paper or leather rendered sensitive with silver nitrate  
 was, of course, known to Wedgwood in 1801, and doubtless  
 subsequently to others. But when he mentions the  
 unknown pioneer in the same breath as Daguerre, our  
 author must have in mind the invention of a process of  
 producing lasting "sun-pictures." Are we to suppose that  
 when English and French photographers visit the Dresden

Exhibition next year it will be to inspect the work of one who predated not only Daguerre, but his colleague Niepce and his contemporary Fox Talbot!

**Orthochromatizing Plates By Bathing.** Apparently as a result of Herr Valenta's recent paper on alcoholic solutions of dyes for orthochromatic sensitisers ("B.J.," October 4, 1907), some further experiments in the same direction have been made by Herr Paul Thieme, and are described in the Berlin "Photographische Mitteilungen." It is found that plates sensitised in the alcohol bath must be rinsed with water, or they show spots from drops of the dye solution left on them. But if water is used for rinsing, the cheaper "denatured" spirit cannot be used for the dye bath. Hence Herr Thieme preferred to rinse with alcohol, which removes dye from the surface of the film, washes off particles of dust, and further accelerates the drying of the plates. Using a solution of the dye-sensitiser in water and rinsing in alcohol, the plates were found to dry in an hour and a half. The author, from a series of experiments, decides on one or other of two procedures:—(1) Sensitise in an aqueous dye bath and rinse in two successive baths of denatured spirits, the first to remove the larger proportion of dye and the second to remove drops of dye solution; (2) if very rapid drying is required, the plate, after being sensitised in an aqueous bath, is allowed to stand for thirty minutes, then bathed for five to six minutes in spirit, and then rinsed in a second bath of spirit.

#### The Analysis of Soda-Sulphite.

We recently published an extract from a contemporary journal devoted to matters chemical, in which the writer sought to prove that anhydrous soda-sulphite is not twice the strength of the crystalline variety, weight for weight. He tested three samples. A commercial sample showed 94.5 per cent. of pure sulphite; a recrystallised sample showed 96.25 per cent., and the anhydrous showed only 84 per cent. He suggested that the anhydrous sample probably showed up badly on account of its being not quite dry. Probably it was not, but the tests prove nothing in any case. A commercial sample of sulphite that shows 94.5 per cent. of pure sulphite is most unusually pure, and, therefore, the comparison is of no value. We have tested many varieties of sulphite, and have met with recrystallised varieties that only showed 84 per cent, while 96 per cent. is very unusual. A casual test of three samples only is quite valueless for comparative tests, and if this experimenter had taken all the varieties he could get of each quality and averaged the results, we have no doubt that he would have come to different conclusions, provided his tests were properly conducted. In any case, however, the volumetric testing of sodium sulphite is an operation that requires particular care, and it is not quite such a simple operation as many seem to imagine. We believe that some rely on a simple titration with iodine conducted in a somewhat casual fashion, and without taking any precautions against the effect of possible impurities. All sulphite contains alkali or alkaline salts, which, if allowed to remain, render the titration more or less uncertain, and 'hypo' is by no means an 'impossible' impurity, especially in a commercial sample from 'ordinary stock.' A high reading from what may reasonably be expected to be a poor sample is always suspicious, and we have grave doubts with regard to the accuracy of the test in the case of the commercial sample quoted.

#### Moser's Images.

In 1842 L.-F. Moser discovered that it was possible to obtain visible images on a polished glass of a coin or other metal object which had remained in contact therewith, or that by merely

writing on glass with a metal point, which did not scratch the glass. He further pointed out that actual contact between the metal and glass was not necessary, and the action he ascribed to "invisible light." In the following year Waidele ascribed the action to the gas occluded on the surface of the metal. This subject was investigated by Niepce de St. Victor, Laborde, Colson, and others, of whom ascribed the action to invisible light. W. Russell, in 1898, first published his researches on the action of wood and other organic substances on dry plates, and in the following year suggested that the effect was due to the hydrogen peroxide evolved. Lengyel had already suggested that the metal decomposed the atmospheric aqueous vapour, and that the hydrogen evolved formed the images. Blaas and Czermak suggested radiative activity, and Kahlbaum and Steffens suggested that the emanation was only caused by gravitation.

#### Positive and Negative Moser Rays.

Piltchikoff two years ago—1906—published an exhaustive paper on the subject, and opposed the view that the results were due either to metallic emanations or hydrogen peroxide. He upheld Moser's views, but differentiated between positive and negative rays. The former he called those which produced an invisible image on dry plates. These he found to be emitted by manganese, aluminium, zinc, cadmium, tellurium, selenium, iron, cobalt, nickel, boron, lead, antimony, tin, and colloidal silver. Negative rays were those emitted by osmium and tantalum, which reversed the previous light action. Copper and brass were found to be without any action. He also found that in absolutely dry air, or in a vacuum, very few metals emitted the rays, and that more were given off in damp air.

#### Ions, the True Cause.

Fräulein Légrády has now carried the subject much further, and ascribes the action to hydrogen ions. The full text of her paper appears in the current number of the "Zeitschrift für Wissenschaftliche Photographie." Sheets of metals were separated from dry plates by small glass rods, two millimetres thick, a plate being placed above and below the metal. The conclusions come to are that the metals *per se* have no action on dry plates, moisture being essential. Neither hydrogen peroxide nor metallic vapours are the cause, but ionised hydrogen. Many metals give two kinds of images, but in the same gaseous atmosphere the images are always the same. Black images above and below the metal are given by aluminium, magnesium, nickel, and zinc. Dark images above and below are given by silver, cadmium, manganese, and lead. Cobalt gives a black image on the upper plate and none on the lower. Gold, copper, iron, platinum, and mercury are without action. The practical application of the above facts lies, of course, in the construction of changing-boxes or other receptacles for dry plates.

#### Liquid Filters.

Liquid filters are probably only used for colour work in studios and occasionally in dark-room lamps. It is often assumed, however, that increase in concentration and increase in depth or thickness of the solution are reversible factors, an assumption founded on Beer's law that "increasing the concentration of a solution is equivalent to a like increase in thickness." Very little attention has been paid to this in photographic literature, but the researches of Walter, Nichols, Merritt, and Wick prove that this law does not hold good except for very dilute solutions. This subject was investigated at some length by Miss Wick last year, and her experiments prove that Walter's conclusions are correct. In

ry dilute solutions there is what he calls "complete solution," in which the molecules exist in a separate state. Above a certain concentration, however, the so-called "critical dilution," the colouring matter exists in "molecular groups," and the result is "incomplete" solution. The conclusion is that in the case of dilute solutions the coefficient of absorption increases in direct proportion to concentration. For concentrated solutions, this proportion fails, the concentration increasing more rapidly than the absorption.

\* \* \*

**Further confirmation.** The above facts are confirmed by a paper, in the current number of the *Physikalische Zeitschrift*, by Stanislaw Kalandek of the University. This experimenter has examined several dyes, which are used as photographic filters, such as methylene blue, crystal violet, eosine, etc., and his results, given in very voluminous tables and many diagrams, completely confirm the results of the above-mentioned investigators. Briefly, his conclusions are that increase of concentration is not proportional to a corresponding increase of thickness, and that increase of concentration causes a greater shift of the absorption than increase of the thickness of the film. Incidentally, it may be mentioned that Kalandek proves that when a dye is dissolved in a liquid of greater refractive index, there is a shift of the position of maximum absorption towards the red end of the spectrum. This is confirmatory of Kundt's law, which is usually quoted as an explanation of the shift of the sensitising maximum of a dye, compared to the absorption maximum of its solution.

\* \* \*

**Stains on collodion prints.** For some reason or other many workers seem to be troubled with what they call stains when using collodion papers, and we frequently receive specimens with requests for information as to cause and best method of prevention. Sometimes samples of unused paper are sent for test, in which case our own prints are generally quite free from stain, and the paper shows no sign of defective manufacture. The only thing clear, as a rule, is that the trouble is due to some local circumstance that we are quite unable to indicate without a fairly intimate knowledge of the complainant's methods and of his work-room. Some examples are clearly due to dirt, but a fairly common form of mark is not what we should call a stain at all. It is much more like a partly bleached out patch, and the inference that it is due to chemical cause is obvious. This subject was discussed in our columns about two years ago, and a very prolific source of trouble was indicated by several of our correspondents. That cause is drying the prints between blotting-papers. In some cases the blotting-paper is in use at the start, in others it has gathered impurities by use. A sheet that has been used upon one imperfectly dried or washed print may very easily damage all that are subsequently brought into contact with it. It is very noticeable that these markings are almost peculiar to collodion prints, with which the use of blotting-paper is usual, and that the complaints generally concern self-drying papers, with which the fixing is very likely to be undisturbed. The fact that stains can be, and are, caused in this way is undoubted, but whether this is the cause of any particular marking on some print sent to us, we, of course, cannot determine. As a rule, we are not told whether blotting-paper has been used or not. We suggest that correspondents should make the following test themselves before asking for information. Cut a print in half, and let one half dry naturally while the other is dried with the blotting-paper used for previously spoilt prints. This is a test that they alone can make, and it should settle the point at once.

## WHITE OUTLINES ROUND DARK OBJECTS IN PRINTS FROM DRY-PLATE NEGATIVES.

LAST week, in our "Answers to Correspondents" column, we dealt with a familiar phenomenon that, owing to peculiar circumstances, had assumed a very unusual form. The effect was interesting in itself, but also by reason of the fact that it clearly indicated which of two explanations very frequently put forward is the correct one. When a dark object, such as a chimney-stack, is backed in a photograph by a light background, such as the sky, it often happens that a quite white outline is visible all round the dark object. Two explanations have been offered of this appearance. One is that it is an effect due to the relief of the image. The white line is said to be produced in printing owing to some optical conditions that we confess we have never been able to understand. The other explanation is the one we gave in our answer, and that—namely, that the oxidised developer over the light tone is replenished from the unused developer in contact with the part of the film representing the dark object, as well as from the bulk of the solution, hence development in the light tone proceeds more rapidly in the immediate neighbourhood of the dark object. In the photographs submitted to us the white line was clearly apparent, but in addition to it there was also a long white streamer ascending from every dark object in the view. For example, in one case a telegraph pole not only showed the white border line, but also a long white streamer ascending from its top right over the sky, the form of the streamer being just that of the vertical shadow that such a pole casts on a misty night when a light is behind it. In these photographs a similar streamer of greater or lesser length was visible over every dark object, so that all suggestions of leaky dark slides, etc., were out of the question. In every case the streamer was clearly a development of the white border effect, and therefore it was apparent that the optical theory of the white border could not hold good. As a matter of fact the plates had all been slowly developed vertically in a tank with a diluted pyro-soda developer, and it was quite evident that these unusual streamers simply showed the course taken by the fresh developer from the shadows as it diffused into the exhausted developer over the light. If the developer had been kept in motion such an effect could not have been produced. This suggests that tank development may at times give very undesirable effects, but this particular effect being so unusual, and tank development being so common, we are inclined to think that the developer used must in some way affect the result. The white border line does not seem to be invariably produced even when the conditions apparently favour it. In theory we might expect it to appear in all cases when the developer is not kept in motion, but we do not think it does always put in an appearance in these circumstances.

## EXPOSURE WITH VARYING SCALES OF ENLARGEMENT.

It is very often supposed that if the exposure for one particular degree of enlargement is once accurately determined, then the exposure for a different size image can be ascertained correctly by a simple calculation. It can be, to a certain fairly close degree of approximation, if the conditions are favourable and the change in scale is not very great, but it very often happens that the conditions are so unfavourable as to render the results quite misleading, and in very few cases are they absolutely correct. When the scale is varied the distance from lens to image, and also that from lens to negative, are both altered. These changes are the only ones taken into account in the calculations, but there are others that may affect the result

seriously. In the first place, if the alteration of scale is anything considerable, the light has to be readjusted; it must be drawn back from the condenser if the scale is increased, and pushed nearer to it if the scale is reduced. This means that the condenser collects either less or more light, and that the negative is therefore either less strongly or more strongly illuminated, which factors are left out of account in the calculations. Then, again, if the change in scales is only slight, it may not be necessary to move the light at all, but the projecting lens will have to be racked, either farther from or nearer to the negative, with the result that it intersects the cone of light from the condenser in a different place. If in one position it only just allows the cone to pass through; in a nearer position some of the light will be cut off by the lens mount, and less will reach the print. By drawing the light back (to narrow the cone) we remedy this defect at the expense of reducing the brilliancy of the illumination of the negative, so little is gained. It is obvious that the diameter of the projecting lens is an important factor, but as anastigmats

of small diameter are more popular than large diameter lenses of inferior correction, the conditions described often occur. Yet another difficulty arises when the lens is racked out to reduce the scale of the image. The light is then brought nearer the condenser, but the gain in illumination is more or less counteracted by the fact that the cone of light from the condenser then becomes so large in diameter that it will not pass through any ordinary size lens. Properly a different condenser of larger focal length should be used for very long extensions, but, as a rule, the ordinary enlarging lantern is only provided with one condenser, which has to serve for all purposes, from making a 15 by 12 enlargement down to the production of a lantern slide. So far as evenness of illumination is concerned, the one condenser will serve well, but it is not adapted to give a brilliant illumination in all circumstances, hence calculated variations of exposure are certain to break down. It is then necessary for the worker to re-ascertain the exposure by the usual methods if he wishes to vary the scale to any considerable extent.

## TESTS OF INSTANTANEOUS SHUTTERS WITH AND WITHOUT APPARATUS.

[Success in instantaneous work is as much dependent on knowing accurately, or within reasonable limits, the actual speeds of the shutter as knowing the speed of the moving object. There are, of course, many methods of timing shutters dependent on the use of more or less elaborate apparatus, but most of them are beyond the reach of the average worker; possibly, therefore, the following suggestions by M. Frank in "Photographische Korrespondenz" may be useful.—Eds. "B.J."]

THE first method is based on the comparison of the densities obtained by exposing a plate on a well-illuminated white surface for varying times, and although the idea is not original, it is worth attention.

One half of the plate is to be covered with an opaque card in the dark-slide, and the plate exposed in the camera on an evenly illuminated white card for exactly one second. The card should then be shifted so as to cover the exposed half of the plate and it will be found more convenient if the card is placed at right angles to the direction of movement of the sliding shutter of the dark-slide, the dark-slide being again placed in the camera, and the shutter withdrawn for one-tenth of its length, and the instantaneous shutter released ten times. The dark-slide shutter should again be lifted one-tenth, and the shutter again released ten times, and this repeated till the whole of the plate has been exposed. The result will be on development as shown in the following diagram—that is, one-half of the plate will show

10	20	30	40	50	60	70	80	90	100	Instantaneous Exposure.
1 Second Exposure.										

a density obtained from one second's exposure, whilst the other will show a series of densities obtained by 10, 20, 40, etc., exposures through the shutter. It will then be easily seen how many times the shutter has to be released to give density equal to one second's exposure, and this will give the speed of the shutter. For instance, if the density given by 90 shutter exposures was the same as that from one second's exposure, then the speed of the shutters was one-ninetieth of a second.

The disadvantages of this method are that it requires considerable time, and if the shutter is one of high speeds, such as 1/800th of a second, so many exposures being effected so rapidly one after the other may put a strain on the shutter mechanism.

A preferable plan is to utilise the well-known law of the increase or decrease of the light by increasing or decreasing the diaphragm aperture. To utilise this principle it is only necessary to release the shutter once with a large aperture diaphragm, and then to give successive exposures, each of one second's duration, with a series of diaphragm apertures in known ratio.

If, for instance, the lens was working at F/4 as the largest aperture, an instantaneous exposure would be made with the shutter on one half of the plate at this aperture, and on the other half would be impressed a series of exposures each of exactly one second's duration, with the various diaphragms. On development one would have a negative which may be diagrammatically represented as follows:—

One second's exposure at							
F/12	F/16	F/20	F/24	F/28	F/32	F/36	F/40
9 times.	16 times.	25 times.	36 times.	49 times.	64 times.	81 times.	100 times.
Instantaneous exposure at F/4.							

If on examination of the negative it was found that the density on the field exposed with F/32 was the same density as the instantaneous exposure at F/4, then obviously the shutter was working at 1/64th of a second.

Obviously any series of diaphragms can be used, and this method is much simpler than the first. The only advantage is that one must use a mask with a different aperture for each exposure, but this can be easily overcome.

Instead of using the above methods with rectangular fields it is possible to use a central circle for the instantaneous exposure with the largest aperture, and then, covering this up, to use an outer concentric mask with a cut-out sector, as shown in Figs. 1 and 2.

Fig. 1.

Fig. 2.

If the shutter works at such high speeds as to require very small diaphragm apertures, which are not advisable, then the shutter may be released a given number of times, and this used as a factor in estimating the final results. For instance, supposing that the shutter worked at 1-1,000th of a second, and it is let off ten times, the density would be equivalent to an exposure of 1-100th of a second.\* If, then, this were adopted, and the resultant negative the density with F/32 was equal to that given by the shutter exposure, the latter would be not 1-64th, but 1-640th, because ten exposures, each of 1-1,000th of a second are given.

It is also possible to combine the two methods by exposing the whole half of the plate for exactly one second, not with F/4, but with F/12.6. As this stop only passes one-tenth of the light of F/4, the exposure will be equal to one-tenth of a second with F/4. It will not then be necessary to expose the strips ten times with

Theoretically this argument is erroneous, as the result of a series of brief intermittent exposures is not exactly comparable to one exposure of a length equal to the sum of many intermittent exposures. Practically the point may be neglected. Eds. "B.J."

the shutter, but only once. Also, instead of exposing for one second at F/12.6 (1-10th of a second at F/4) an exposure of ten seconds at F/40 can be given, and greater accuracy in timing thus secured. As an exposure of one second at F/40 equals 1-100th at F/4, the method is capable of application to times shorter than 1-100th of a second.

The use of this method, with varying stop apertures, is less accurate for diaphragm shutters than for those working in front of or behind the lens, or immediately in front of the plate.

The old methods of photographing a rotating wheel with a white or brilliant object on the periphery may be used. The speed of rotation should be exactly one second, and if an exposure be made through the shutter, the length of the arc of the peripheral object to the whole circle will give the duration of the exposure. Obviously, the length of the white object must be deducted from the length of the arc, but when mirrors in ball form are used this is not necessary. This principle may be carried out in many ways. One may, for instance, use the back wheel of a bicycle, on the edge and centre of which is fastened a bright or white object, the wheel being revolved exactly once a second by means of the pedal crank. It is quite possible, too, for a man to swing a white stick in front of a dark cloth, using the shoulder as the centre. In place of the stick a piece of burning magnesium ribbon may be used in a perfectly dark room. Black circles with a white radius may also be used, or a series of small silvered balls may take the place of the white radius.

The principle of a dropping object may also be employed, and in this case it is necessary either to use a table of the rate of dropping or employ a somewhat tedious mathematical calculation of the increasing acceleration of the fall due to gravity.

All measurements with shutters made with a lens are inaccurate in so far as they only apply to the actual lens used. As (with individual lenses) the decrease of illumination varies towards the edges so will the length of the arc of a moving object vary as this falls nearer to or further from the edge of the plate. The differences are not so great, however, as to be of much moment from a practical point of view.

MAX FRANK.

## ON THE COLOUR OF UNTONED PHOTOGRAPHIC FILMS.

(A Paper in "Eder's Jahrbuch.")

Experiments first begun with Dr. Ed. Schloemann\* have given results which may perhaps be useful practically, as it is possible to obtain very brilliant coloured films of absolute permanency. The duration depends probably, as was suggested in the previous paper, on an optical resonance process in the silver-gelatin system, which is naturally completely insensitive to light, oxygen, etc.

A fine-grained silver bromide emulsion which, depending on the exposure and time of development, will give with certainty the following deep saturated colours by transparency is very suitable.

### DEVELOPING SUBSTANCE.

#### FERROUS OXALATE.

Red.  
Orange.  
Yellow.  
Green.

#### ADUROL.

Ruby Red.  
Blue.  
Violet.  
Purple.

With ferrous oxalate blue and purple tones can sometimes be obtained, but they are not very pure.

The colours seen by reflected light, in the case of the red films, is distinctly green. With the others the complementary colour is less distinct; sometimes some of the films, for instance certain blues, appear black by reflected light.

The emulsion has a fairly fine grain and low sensitiveness; it can be manipulated without a dark-room.† Plates coated with it give good density and beautiful colour effects when used as transparencies. Papers coated with the emulsion show, when fully developed,

complementary colours in the high-lights and shadows, for instance, red high-lights and green shadows, as the former gives practically the colours by transmitted and the latter by reflected light.

The colours alter when the films are soaked in water, but this can be prevented by strongly hardening. Microscopic examination shows the following structure of the films in the dry and the wet

Colour of the film.	Dry.		Wet.
	Ground.	Grain.	
Red.....	Red.....	Black.....	Unchanged.
Yellow.....	Yellow.....	".....	"
Green.....	Green.....	".....	"
Blue.....	Colourless to bright blue	Brown black...	Red "Black.

No change of colour appears when the film is carefully scratched off, melted, and diluted with five times its volume of 5 per cent. solution of gelatine, and again coated. The purpose of this is to increase the distance of the grains or clots.

We have also tried to destroy the clots by boiling the film for five minutes. After cooling and again coating the same colours appeared. The clots must therefore have considerable stability. Treatment of the films with sodium and calcium chlorides had no effect.

Intensification with silver (physical) developers deepens the colour with a slight change. The following changes were obtained:—

Bright red → deep red.  
Bright green → dark green.  
Yellow → orange → red.  
Blue → dark violet.

Reduction generally causes a lessening of the saturation with the

\* "Eder's Jahrbuch," 1906, p. 146.

† From this statement, and from the great variation in colours obtainable, one would be inclined to hazard the statement that the emulsion is one of the well-known "gaslight" varieties. These are usually chloride or chloro-bromide emulsions. Eds. "B.J."

blue, green, and yellow films. This occurred with those films developed with ferrous oxalate. These ruby red films developed with adurol showed striking changes with various reducers, as follows:—

Reducer.	Colour after reduction and drying.
Farmers .....	Bright red.
Ceric sulphate .....	"
Potassio-ferric oxalate .....	Crimson to red violet.
Ammonium persulphate .....	Blue violet (seldom crimson).

The very remarkable changes of colour after treatment with persulphate led us to examine the reduced films more carefully. Whilst

most of them showed little change the blue plate obtained from ruby red preparation gave the following results:—

Transmitted colour .....	Blue Plate.	
	Dry.	Wet.
Ground .....	Blue .....	Red.
Grain .....	Colourless .....	Red.
	Blue .....	Black.

The reduced plates, when treated with a silver physical intensifier gave a more saturated colour; the blue plate obtained by reduction with ammonium persulphate did not give the original ruby red, but rather a dark violet.

DR. KARL SCHAUER.

## AN INDICATOR FOR THE PREVENTION OF DOUBLE EXPOSURES.

In a paper before the last meeting of the "Deutschen Photographen Verein," held at Bremen, a professional photographer, Herr Ed.

Fig. 1.

Schutze, of Schöningen, described the following attachment for dark slides of either the book or solid pattern, whereby the shutter is

Fig. 2.

locked after it has once been withdrawn. The diagrams of the mechanism are from the "Deutschen Photographen-Zeitung."

Fig. 1 shows the shutter of the dark slide closed, the dotted lines

indicating its position when partly withdrawn. In this latter case the angle piece, WC, has turned on the pin C, and has brought the other leg of the angle piece into the slot H (see dotted lines at H), pushing the shutter home after exposure, the leg W remains in (Fig. 2), and prevents a second withdrawal of the shutter.

Figs. 3, 4, and 5 show a similar device applied to the metal slide with pull-out shutters. A spring, F, fixed to a pin S, is attached

Fig. 3.

Fig. 4.

Fig. 5.

the hook, H. At P is a small catch, which snaps into the aperture of the spring being pressed down. When the shutter is withdrawn (Fig. 4) the catch P springs out, the spring F straightens itself, and on the shutter being pushed in (Fig. 5) the other leg of the angle piece, H, snaps with the other hook, P, into the opening O, of the shutter, with the result that the dark slide cannot be again opened unless the hook P is released from O, by pressure with the finger on P, whereby the small catch is pressed into the aperture O.

**ERRATUM.**—In our notice of Messrs. Staley's new catalogue last week a literal error of "lens" instead of "list" made it appear that an actual objective might be obtained for the sum of one penny. Much as Messrs. Staley have done in offering high-class lenses at moderate prices, they are disposed to regard the above figure as overstepping the mark.

**AFFILIATION OF PHOTOGRAPHIC SOCIETIES.**—The Secretary of the affiliation writes:—"The newly-elected executive held its first meeting on Friday evening, February 21, 1908. Mr. P. Bale Rider, representing the Birmingham Society, was unanimously elected chairman of the committee for the coming year. The continued increase in the number of societies joining the affiliation is very gratifying, and the committee are systemising the increasing work by forming themselves into sub-committees, each having its special work to look after. Important matters were brought before the meeting, and new arrangements are being concluded with the parent society as to the clerical work involved. Dr. A. R. F.

Evershed has been appointed editor of the "Red Book," and arrangements are being made for a combined outing of affiliated societies early in May, when the North London Society will act as host.

**CINEMATOGRAPH PICTURES OF PHYSICAL EXPERIMENTS.**—Mr. Martin Duncan, who, in conjunction with Mr. Hovenden, has been experimenting with reproductions of physical phenomena for the past five years, has just completed a series of pictures which will be shown for the first time at a series of lectures which will shortly be given by Mr. Hovenden at the London Institution. The cinematograph apparatus originally used by Mr. Duncan was not of sufficiently perfect design to give the exceedingly accurate results that were necessary to demonstrate these phenomena, and the films obtained with it were of little value, from a purely scientific point of view; but at the beginning of this year Mr. Duncan obtained a satisfactory apparatus, constructed specially for him by Mr. Arthur Newmann, with which he was able to obtain results entirely satisfactory.

## THE NATIONAL PHOTOGRAPHIC RECORD ASSOCIATION.

At the annual general meeting of the National Record Association was held on Tuesday afternoon last, February 25, when the president, Sir Benjamin Stone, entertained a company of ladies and gentlemen at the Midland Hotel, St. Pancras Station.

Sir Benjamin Stone, in proposing the adoption of the report, delivered a short address on the present position of survey work on some general tendencies in photography. He thought that the report as to the work of the National Association and that of the societies who were locally engaged with the same object was satisfactory, though he felt that the public had not begun to understand it was being done. The labours of those who were now making record photographs would be better appreciated by future generations than they were by those now living.

During the past few years, proceeded Sir Benjamin, the daily press, by its reproductions of photographs of passing events, had constituted itself in some measure an instrument of photographic record, but its work was done so hurriedly that it was usually very faulty, and, moreover, a print on paper such as daily journals were printed on could not be regarded as permanent. A further self-constituted exponent of record photography was the traveller, who with little knowledge of photography returned home from his rambles with photographic souvenirs of the places he had visited. These obtained a fictitious value in his eyes, and so led him to write a periphrasis (to go with them), which was even worse in its way than the photographs. Sir Benjamin Stone deplored the present-day tendencies which made for a lower standard of photography. There were the small prizes awarded in photographic society exhibitions. The work of anyone who had received such a prize was unfortunately regarded as necessarily good. Another cause of bad photography was the award of prizes by daily and other papers for the most miscellaneous subjects, photographed in many cases by persons who had no knowledge of the proper procedure.

He (Sir Benjamin) viewed the progress of record photography with the greatest solicitude, because he believed it to be as useful a work in which anyone could engage. He looked forward to the time when photography would be largely and officially employed by some central organisation, which would distribute throughout the land for educational purposes copies of photographs which would be a part of the history of the world.

In seconding the adoption of the report, Mr. C. E. Fagan mentioned the desirability of classifying and making more accessible for inspection the 4,000 photographs already deposited in the British Museum. He referred to the valuable work done by Sir Benjamin Stone in making photographic copies of objects and specimens in the South Kensington Museum. Such work was certain to prove of national use.

Mr. Topley, in proposing a vote of thanks to the council, hoped that steps would be taken to afford intercommunication between the various bodies engaged in record work.

Mr. Hector Maclean, in seconding, suggested that an excursion-isting of the Association would be productive of good.

Sir Benjamin Stone was re-elected president on the proposition of Rev. F. C. Lambert, seconded by Dr. Woodward.

Other propositions and votes of thanks brought the meeting to a close.

The following is the report of the Council:—

The Council of the National Photographic Record Association have the pleasure of presenting their Tenth Report, and it is with satisfaction to all to note, since the formation of our Association in 1897, the growing interest taken in Survey Work not only in our own country but in the Colonies and abroad. Our own collection of prints deposited in the British Museum now numbers 4,162, and in addition to this many other Societies throughout the country have deposited large collections with their local Museums and Libraries.

Since the last Report we have received for our own collection 1,000 prints, 100 from our President, Sir Benjamin Stone, including a series of that most historical mansion, Holland House, built in 1697, and in which have resided Lord-General Fairfax, J. Addison, etc. Audley End, another historical mansion near Saffron Walden, referred to by Pepys, who seems to have been particularly struck by the cellars—"where we went down and drank much of liquor; indeed, the cellars are fine"—also of Hengrave Hall,

Suffolk, Little Aston Hall, Perry Hall, and New Hall, Warwickshire. From Colchester, part of the Castle and the ruins of St. Botolph's Priory; Layer Marney, the Towers and the Church and Marney Tombs; Cambridge, King's College and Trumpington St.; Bury St. Edmunds, the Abbey Gate House, etc., some of the old houses of Sutton Coldfield; Church at Hoar Cross with its fine screen; Clare Church with the sundial and its quaint inscription, "go about your business"; Copford Church, Essex, North Door upon which remains of human skin were discovered, and some fine examples of old plaster work on the fronts of old houses at Clare, Suffolk, and Saffron Walden, and the historically interesting Church of Navesyn, Ridware, containing the Chadwick family Memorial, the tombs of Sir R. Malveysin and Sir W. Handsacre, slain at the battle near Shrewsbury, July, 1403; and a group of the German Burgomasters on the terrace of the Houses of Parliament, May 15th, 1906.

Mrs. Catherine Weed Ward has made a further contribution of 47 Prints, mainly a continuation of her series of fonts, and include photographs taken in Somerset, Warwick, Gloucestershire, Shropshire, Devon, Exeter, and Hertfordshire.

From Mr. G. Bingley we have received a very complete set of 19 prints of the old Church of St. John's, Leeds, including photographs of the wood carving on pulpit, pew ends, and panels.

Mr. E. Scamell has sent in 24 prints of the Temple Church, London, and monuments of Bishop Everden, Earls of Pembroke, and various Knight Crusaders.

Mr. H. W. Fincham has sent in some prints of the Warden's House, Christ's Hospital, pulled down April, 1907, and also an interesting copy of a drawing by J. Cleghorn, 1817, of the old Turnpike Gate which stood in Farrington Road.

Mr. H. Pope has forwarded 11 prints, including views of Wilberforce House, Battersea, where the Committee for the Abolition of slavery used to meet.

Miss Niblett has again added to our collection, including portrait of John Lee, one of the original Chartists, and his house, and the school-house at the Chartist settlement at Redmarley D'Abitot, Worcestershire.

From Mr. Collinge 10 prints, including views of the house at Hoole, Lancashire, where the Rev. J. Horrox observed the transit of Venus in 1639, and views of Astley Hall, Lancashire, where Oliver Cromwell slept. From Mr. O. W. F. Thomas prints of Haddon Hall and Wingfield Manor; Mr. Blinco, a series of the cross at Leighton Buzzard; one by Mr. E. Pater of an interesting old fireplace at Wycollar Hall, Lancashire; and two sets of present day work and workmen, one by Miss Wall, constructing the electric tramway at Southport, and one set from Mr. Marshall, the making of a horse-shoe; and 59 from the Hon. Secretary, of the Churches of Essex and Sussex, and of the Leez Priory, Essex, founded in 1229, and granted to Sir R. Rich, Solicitor-General, created in 1547 Baron Rich of Leez.

Many important Survey Societies are now at work. We would refer to the Photographic Survey of Warwickshire, with headquarters at Birmingham; Photographic Survey of Edinburgh and District, Secretary, J. Oliver; Photographic Survey of Essex, Miller Christy, (F.L.S.), President, V. Taylor, Secretary, who held their annual meeting at Kelvedon last June, when an address was given by Sir Benjamin Stone; Photographic Survey of Kent, H. E. Turner, Hon. Secretary; Photographic Survey and Record of Surrey, President, Hon. Henry Cubitt, who have, according to their last report, a collection of 2,340 prints deposited at the Public Library, Town Hall, Croydon, and that the public are now beginning to appreciate record work is proved by the fact that during the year there have been many hundreds of references to the collection; Photographic Survey of Sussex, President, Duke of Norfolk, their collection of prints, negatives, and lantern slides, together over 2,000, are deposited at the Brighton Public Library.

The Photographic Survey of Worcestershire, Mr. W. Harris, Hon. Sec., and other Societies in Herefordshire, Yorkshire, Leicestershire, etc.; also many of the Photographic Societies have instituted Survey Sections. The North Middlesex Photographic Society are forming a good collection of the neighbourhood of Hornsey and district; the prints are deposited at the Public Library, Hornsey. And the Southampton Camera Club are working to obtain a thorough survey of the town, which contains so many interesting old bits. Although so much work is in progress, it must still be a source of

regret that such a mine of wealth as is in the possession of the amateur photographer still remains untouched, neglected, and of no possible use to the public, and we would again urge all photographers to look through their stock of negatives, and forward prints either to us or to their local collections, as, even if the prints may not be of first quality as photographs, they may in time be invaluable as a record.

The programme has just been issued of a most important Photographic Exhibition, to be held at Dresden, in 1909, under the patronage of His Majesty King Frederick Augustus of Saxony, and the President of the Committee, His Royal Highness Prince John George Duke of Saxony, in which exhibition will be a section devoted to Record Work. The English Committee have referred this matter to us to select a representative collection of the work done in this country, and we trust this will do much to stimulate the interest in the subject, not only here, but on the Continent.

With regard to the negatives bequeathed to the Association by the late Mr. R. P. Brereton, referred to in our last report, prints from them are deposited in the British Museum in the MSS. Room, and the negatives have been deposited in the Museum of the Architectural Association, and are, we have been assured, of great value to the students.

The Association desires to record its thanks to the Press for the many notices they have given of the work, and especially to the Proprietors and Editor, Mr. G. E. Brown, of "The British Journal of Photography," for having arranged an Exhibition of Record Work at their offices in Wellington Street, last April and May, when we exhibited 108 prints of miscellaneous subjects to illustrate different phases of the work, and prints were lent by Sir Benjamin Stone, Mrs. Wood, Messrs. H. W. Finchan, G. Bingley, E. Scamell, the Hon. Sec., and the late Mr. Armytage.

We would again appeal to the public for liberal support, as with a strong fund to draw upon, we know of many professional men having large numbers of valuable negatives from which we could obtain prints at cost price, and we would again urge the amateurs to contribute freely prints from any suitable negatives they may have in their possession.

#### THE SCOTTISH FEDERATION ANNUAL MEETING.

The fifth annual meeting of the Scottish Photographic Federation was held in the Grand Hotel, Aberdeen, after the opening of the Salon. There was a good attendance of delegates and associates, presided over by Mr. S. Stewart, F.I.C. (Kirkcaldy Society), vice-president of the Federation.

The secretary submitted a report, which showed the maintenance of interest in the various branches of the Federation's work. The treasurer's annual financial statement showed a balance in favour of the Federation of £35. It was decided to leave the settlement of the locale of the next Salon, and also the selection of president, to the Council.

Office bearers for the season were elected as follows:—Vice-presidents, Frederick W. Kay, Aberdeen Association, and A. Symon, M.A., B.Sc., Wishaw Society; secretary, John B. MacLachlan, Blairgowrie and District; treasurer, Archibald Campbell, Dundee and East of Scotland; auditors, J. Murdoch, C.A., and R. C. Thomson; council, R. Milne, Paisley Philosophical Institute (Photo section); R. Marshall, Grangemouth; W. H. Wilson, Glasgow Southern; Vanessa C. Baird, Dundee and East of Scotland; J. D. Ross, Brechin; J. Bentley Philip, Aberdeen Century; R. Thomson, Midlothian; and Robert K. Holmes (associate). It was agreed that the annual excursion be held at Stirling. At the Council meeting held afterwards J. D. Ross was unanimously re-elected portfolio secretary, to fill the vacancy caused by the retirement of Dan Dunlop; Robert Marshall was appointed lantern slide secretary; Mr. P. D. Nairn was appointed excursion secretary.

**SCOTTISH NATIONAL EXHIBITION.**—In regard to the photographic section of the forthcoming Scottish National Exhibition, Mr. W. Crooke, of Edinburgh, asks us to say that application for forms should be made to the manager, 45, York Place, Edinburgh, and must be returned to him by March 1. All exhibits must be delivered by April 1.

#### DEATH OF MR. HORSLEY HINTON.

Our readers and photographers throughout the world will be surprised and shocked at the announcement of the death of Mr. Horsley Hinton, which took place on Tuesday last at his home Woodford, Essex, after an illness of only a few days. Mr. H. returned last week from Aberdeen, where he had visited the Scottish Salon. In journeying home, it is supposed, he caught a chill, which showed such serious signs as to compel him to cancel several engagements. His condition developed still more alarming symptoms, and death, reported to be due to brain fever, took place on Tuesday morning last, at 10 o'clock. At the time of his death Mr. Hinton was forty-five years of age.

In the death of Alfred Horsley Hinton the photographic world loses a dominating personality and an indefatigable worker. For the past fifteen years Mr. Hinton, as editor of the "Amateur Photographer," writer, lecturer, and organiser, has taken an important share in every movement which has stirred the ranks of photographers. Entering photography through a commercial firm of dealers in photographic goods in the City of London, he at once showed aptitude for writing and his championship of photography as a branch of fine art by editing the "Photographic Art Journal."

Photograph by [Fredk. H. Evans.  
THE LATE A. HORSLEY HINTON.

periodical which ran for four years. During this period Mr. Hinton's writings on photography as an art appeared in many publications and his unremitting claims for the recognition of the camera as a means of pictorial expression did not lack the productions of his own instrument to give them force. Apostles of pictorialism in photography there had been before, but none who so persistently and forcefully, with camera and pen, waged war against those who would have denied photography a place amongst the arts. Mr. Hinton was more than an important factor in the movement towards what is known as "pictorial photography." He was essentially its creator and he popularised it among the large body of amateur photographers whom he could address week by week. Himself a skilled worker in the photographic processes, Mr. Hinton's writings, especially in the earlier part of his career, were distinguished by the communication of much detail of manipulation, conveyed with a literary style of considerable charm and vigour. In recent years more engrossing duties compelled him to photograph less and write more, and his signature therefore appeared most frequently over appreciation of the work of others, who, but for his encouragement, would never have applied the camera to pictorial ends.

On the inauguration of the Photographic Salon Mr. Hinton was one of its most enthusiastic supporters, and for some years, after the death of Mr. H. P. Robinson, its moving spirit.

Hinton's writings were not confined to photographic periodicals. He was a regular contributor to the daily and weekly newspapers, and his article on "Pictorial Photography" in the "Encyclopædia Britannica" was from his pen, and he was the author of a number of text-books, several of which have enjoyed a wide reading, and have been translated into other languages.

For those who knew him personally the shock comes with a dull, lingering sense of personal loss, but behind and beyond that is the feeling of the great loss to the photographic world. Few men, in the walk of life, have combined such versatility, consistent quality, and enormous quantity of personal output. While much of his life was before the public, there was much, also, with which he was not publicly associated, and few people, possibly no one, can have any correct idea of all that he achieved. His writings alone would have been a creditable output for any man; but, in addition, he was an unusually strong and consistent pictorial photographer, an accomplished and prolific draughtsman-illustrator, and an organ and administrator in exhibition and society work to an extent not recognised by few. His death lends a pathetic interest to the last conversation we had with him, in which he spoke of the prospect of another fifteen years of crowded life. Mr. Hinton was a lover of his home and his garden, and one constant vision of his future when he would be able to spend more time in those genial surroundings. Much of what should have been his leisure was spent in honorary work for photographic associations, for he never unsparing of his help when it was asked of him. His sensitive nature led him, at times, to both give and take more than was intended, and his unflinching character made him persistent in what he believed to be right. In photographic matters he was involved in many a stern fight, and was often both misunderstood and misrepresented, but those who knew him best, and who often his opponents, knew him as a fair, generous fighter, as one who never, knowingly, stooped to mean or unworthy attacks.

His funeral will take place on Saturday at 12.30 in the City of London Cemetery, Little Ilford.

## THE PHOTOGRAPHER'S ADVERTISING.

A Note in the "Bulletin of Photography."

ADVERTISING in any business has become a necessity. If you have a commodity for sale or are producers of a certain kind of work you must let the public know about it. But a profession requires a different sort of publicity from a trade or a business. It would be undignified of a clergyman or a physician to advertise at all, and so kind of advertising employed by a patent medicine vendor would be undignified in a photographic profession. Photography, while a business, and, to a certain extent, even a trade, is also an art, and needs artistic taste and perception to make it worthy of the title.

It is a great mistake to treat a sitter in the same way as a would-be purchaser entering a shop. The shopkeeper does well to secure his customer at all hazards, for he may never see the transient customer again, but the photographer's tactics should be just the reverse. He must not meet his customer, satisfy him, and at once dismiss him; he must at the very start look to future business relations, and must proceed cautiously—not kill him at once with a display of magnificence, but cautiously lead him on. If the customer perceives that the photographer is a sharp man of business the chances are that he will be inclined to go away to another, who impresses him more with his artistic talents. A studio, instead of being a thrifty-looking place of business, should have an air of business relaxation about it, just the place where a strenuous man of affairs would feel as if he had escaped commercial stress and storm, a peaceful haven from bank runs and stocks and finance. A studio should impress one as a place of lounging-place, and should be furnished with everything ministering to ease and comfort, not in the least suggesting that its sole object is to lure the unsuspecting to a purchase—dislikes to be confronted by a human interrogation point, even if dressed as a handsome reception lady—a pleasant place of sitting for a chat with a friend, like the lounging parlours in our department stores, a place of welcome where the visitor never hesitates to enter, a place which establishes friendly relations at once between the visitor and proprietor.

A photographer should look for business through his reputation. He should labour to demonstrate that he stands high in his profession, not by circulating dodgers or penny-stamp envelopes to the "Lady of the House," but by exhibitions of his ability and position in the display of his work, by the taste and skill in the decoration of his studio, by the convincing air of refinement in his furnishings; not by ostentatious show of cheap magnificence and tawdry finery.

The photographer who aims for publicity by grand exteriors, with grandeur in the hallways, grandeur all the way upstairs, grandeur staring the visitor at entrance of the studio, and a blaze of grandeur in the studio itself, makes a grand mistake. Such extravagance of display creates repulsion instead of attraction.

A bright and cheerful studio, full of pictures with appropriate settings and accessories, will attract the refined upper-ten, and will not distract the equally refined but more numerous middle class.

## Exhibitions.

### EDINBURGH PHOTOGRAPHIC SOCIETY.

The annual exhibition of the Edinburgh Photographic Society opened in the Club Rooms, Castle Street, on Saturday last. A decline in numbers was evident, there being seventy-two exhibitors (twenty-seven non-members) and 197 exhibits, including twenty-one sets of lantern slides. A noticeable feature was the very large number of prints in bromide. The judges, Messrs. C. Martin Hardie, R.S.A., Wm. Crooke, and J. Craig Anman, made the following awards:—

Open Class.—Medals: "When London Sleeps," Geo. L. A. Blair, Paisley; "On a Normandy Farm," W. J. Croall, Edinburgh; "The Deserted Mill," Harry Lindoe, Sunderland.

Open Class—Lantern Slides.—Medals; Graystone Bird, Bath; Richard Hancock, Heckford; and Alfred J. Loughton, Notts.

Photographs in Colour.—Medal: Arthur W. Walburn, West Hartlepool.

Members.—Medal: J. D. Paterson (2).

Members (who have not previously gained a medal).—Medals: D. W. Thompson and J. A. Angus.

### BIRMINGHAM PHOTOGRAPHIC SOCIETY.

My heart sinks low when I behold

That poster on the wall.

If such a paraphrase of the poet's immortal lines may be permitted, it is what one might vent upon coming face to face with the rainbow-tinted bill which the Birmingham Photographic Society displays this year. Fortunately one's heart is in the right place again at the first sight of the exhibition, and the meaning of the iridescence of the placards becomes apparent in view of the special feature made of the colour plates and prints.

The Society's annual display, which is well housed in the commodious galleries of the Royal Society of Artists in New Street, was opened by the Lord Mayor at seven o'clock on Friday last. It will remain open until March 2.

In the Great Room is hung the Members' Section, which, good as it is, suffers a little by reason of the fact that many of the more distinguished members have placed their works in the Open Section. This is, not unnaturally, by far the strongest portion of the exhibition. There are also small and separate sections provided by the following local societies:—Aston, Bournville Camera Club, Bournville and District, Brierley Hill, Erdington, Handsworth, King's Heath and Moseley, Municipal Technical School, Small Heath, Walsall, and, lastly, Worcester. Of these the Walsall Society has gained a medal for the best set of pictures sent by the local clubs.

The exhibition further includes a scientific section, devoted chiefly to natural history subjects; an excellent collection of colour-transparencies by the Lumière, Sanger-Shepherd, and Joly methods; lantern slides; a few colour prints, photographs belonging to the Warwickshire Survey, among which are many depicting groups from the recent Pageant; and finally some exhibits of apparatus.

To begin with the Members' Section. No. 1 is "An Old Mart," by G. L. Moore, an antique market-place shelter with a fine timbered roof to which the photographer has turned his special atten-

tion. No. 2 commences a liberal series by Mrs. Barton, who, by the way, has withheld her pictures in this group from competition, and in that course has been joined by Mr. Greatbatch and Mr. Wm. A. Clark. Mrs. Barton's "Hannah: A London Flower Girl," cannot be said to be the picture of a beauty, but her rather vacuous and brutal face has character of a sort, particularly as it is shaded by the type of hat with drooping feathers immortalised by Phil May, and now characteristic of Mayfair, motor-cars, and *le bon ton* generally. But Hannah has nice points of composition and management, besides a breadth of treatment, which is not, as a rule, a strong point of Mrs. Barton's work. Her "Edward Titley, Esq." (No. 8), for instance, has a distressing spottiness of forced lights and accents, quite marring an otherwise good portrait. Mr. E. D. Taylor has won a certificate for his "Evening" (No. 11), a river scene and bridge of happy selection. It is well composed, and has the further merit of a proper recession of planes. "Mary, Daughter of E. R. Carwardene, Esq." (16), is one of Mrs. Barton's happy examples of childhood. The pretty child is delightfully posed and lighted, but the thing is not improved by the utterly unconvincing background, which appears to be painted. In No. 19, R. S. Clarkson has secured an excellent likeness of Mr. Harold Baker, and a certificate to boot. It is, perhaps, just a thought posey—even to the regulation peep of handkerchief from the breast pocket, but the modelling and lighting of the head are distinctly good. The whole thing would perhaps have been better for more virility and strength in its lighter tones. Mrs. Barton appears again in No. 22, "When I'm as Big as You." The anticipation is addressed by a little boy to a hollyhock growing outside a window of leaded lights. Very unfortunately, an angle of these leads fits exactly over the boy's nose, and gives him a parrot's beak. The subject of "Autumn Flowers and Sunshine" (34) is a girl, prettily posed as usual, wherein Mrs. Barton repeats her want of judgment in allowing her print to degenerate into bright flecks upon a dark ground. There surely might have been more "losing and finding," more melting of tones. Even the passages of low tones in this work are "cut out" and flat. Work as admirable in so many ways as is Mrs. Barton suffers more acutely by such drawbacks than would less successful attempts. One of the most engaging of figure subjects here is a young mother and her baby, which Mr. H. W. Rennie calls "Hush-a-bye" (No. 37). It well merits the certificate it has won. The head is charmingly posed and most artistically treated, and the baby is better than babies often are under the eye of the camera. "Lux in Tenebris" (No. 38) comes from Wm. A. Clark, and depicts a dark crypt with one of its massive columns catching a shaft of strong light. The contrast, if not too strong for truth, which is doubtful, is at any rate too strong for art.

The Secretary, Mr. Lewis Lloyd, is to be congratulated upon the atmospheric beauties of his charming little canal scene called "A Waterway" (45). Less sky in W. Howard Coley's "Spring Morning: Poole Harbour" (60) would have resulted in better balance and a less fantastic "panelling" of a good subject, which has an excellent range of tones. His "Close of a Stormy Day" (64) is romantic and true in effect. It shows a lowering sky over a stretch of open country, and the passing of the stormy day has been well and convincingly suggested. P. Bale Rider carries off the medal in the Members' Section with his splendid "Meadow" (72). Here textures are most fascinatingly preserved without any loss of atmosphere or breadth of treatment. The picture has a slight fussiness, due entirely to the nature of its full, rich, and complex subject, made up, as it is, of tall wild-flowers and lacey trees. But a little more massing of the chiaroscuro could perhaps have been attained by a lowering of the point of view. This would have hidden the dark passage between the foreground flowers and the middle distance, or at least have joined up these two light spots.

As usual with the Birmingham Exhibition, the great amount of work submitted from all parts of the civilised world has enabled a most severe selection to be made, with a strong show as a result. The medal goes to E. O. Hoppé for his "Portrait" (111). It is a quietly toned picture of a girl in a large hat, and is quite unusually successful in the perfect taste of its design. Well placed upon the paper, of excellent "pattern," with a delicate but effective scheme of lighting—to say nothing of the charm of its subject—it should rank as an "old master" amongst photographs. Of H. Essenhich Corke's "Swarthy Cheeks and Bold Black Eyes" (109) honourable

mention has been made. Its fine subject deserves it, for it has a rare charm of magnificent physique and statuesque grace and feminine beauty. Its colour is rather heavy, and it has an irritating spot of light upon the left wrist which comes sharply against the dark draperies below the bust. In "Sun and Mist" (126), by A. E. King, a fine atmospheric effect is most happily given. It is that most desirable thing in landscape work—a mood, and is justly certificated. No. 136, "Washerwomen," is sent from Ravenna by L. Farini. Two women bend at their task over a shaded stream, and their largeness of treatment makes one think of Millet. Mr. Mahony is "commended" for her "City Highway" (148), where a broad river, flanked by noble buildings dominated by a dome, furnishes a stately subject. The print is very good in quality, but the water should be lighter under the light part of the city. Another honourable mention is for "Chioggia" (163), by A. Benussi of Trieste. This work shows large boat-sails which partly hide church and other background buildings. Unfortunately, owing to a similarity of tone and texture, it is not easy to see where the begins and wall ends at one part; but apart from that defect, and a little patch of light at each corner, the print is extremely rich, and of captivating "quality" in the technical sense of the word. In this section Mrs. Barton had won a certificate for her "Fates" (140) a work already well known. Its idea, its arrangement, and the quality in the heads are irresistible matters, but the flecked and shiny appearance of the tin-like frocks of the girls is not pleasant. James C. Batkin's "Dispersing the Gloom" (180) shows a good effect of sun breaking through a thick atmosphere on the Thames. It lacks a little firmness in the near parts, and a further interest in the water surface.

A certificate goes to E. T. Holding for a delightful portrait of Miss Ethel McCarthy (183). He shows, also, his "Childhood" (191), a favourite in London last year. It is pleasant also to see Walter J. Clutterbuck's pretty pastoral, "The Little Shepherdess" (184). "The Shepherd" (186), by Fred Judge, is of good style, and a pleasingly composed landscape of open country. J. C. Warburg has two pictures hanging together, called respectively "The Neighbour" and "The Wanderer's Return" (189). The subject of the latter is so fitted for the former title that doubt arises as to the proper numbering of the exhibits. It represents two old men at the doorway of a cottage, and is a print of fine colour and quality and carries a certificate. Another work of good design is Mrs. E. Peake's "The Spell" (195), but it is marred by an excess of contrast in the dresses of the two girls which cuts up disastrously a highly dramatic group. The next certificated work is "Snow Landscape" (201), by Heinrich Hinz. Here a strong blue has been used without the usual drawback to so twangy a tint, and the success of the print is due to the masterly and convincing treatment of a snowy shore where a boat lies in strong sunlight. "Seeing the World" (213) is Mrs. E. Peake's neat title for a little girl studying a school globe—a print of first-rate quality, with a strong impression of light. It is a pity that the child's legs are not accounted for. This also bears a certificate. Next come two of the most successful essays in the exhibition, both gaining medals. The first is "Snow in the City" (220), a Birmingham view, by J. Dudley Johnston, and the other, "While the Daylight Lasts" (223), by James C. Batkin. The latter represents a group of men working upon the under side of a stranded vessel. The idea is by no means new, but the treatment and feeling for roundness of form are welcome after the silhouetted examples of similar subjects that have become fashionable lately. In composition, or rather "pattern," this would be hard to beat. It is somewhat heavily treated, however, and in this respect compares with "Snow in the City," which is delightfully subtle and tender. R. Dührkoop contributes a group of his famous portraits, most, if not all of which have already been seen in public. He obtains a medal for his "Portrait of the Poetess" (236), a lesson in simplicity and restraint, and a certificate for "Conversation" (235), which, it will be remembered, represents a lady and gentleman sitting upon a sofa. J. C. Warburg, who is to be congratulated upon the strength of his work in this exhibition, takes a medal for his portrait of an elderly lady at a piano. It is one of the richest in quality amongst this class of work; the hands and the head are excellently lit and modelled. He calls it "A Song Without Words" (263). A lady and two little children, cheering from a window decorated with festooned drapery, bears

The title "When Johnnie Comes Marching Home" (280). The photographer, D. Murray, is to be pitied on account of the festoons, but congratulated upon the general charm and richness of this engaging little work, which has secured a certificate. H. T. Winterhalder had the ill-luck to get the glass of his picture badly starred. But as the work received honourable mention, the usual slip of paper was attached with the word "Commended." A wag added another which said, "but not mended." The title of the picture is "Sunlight on the Minstrel Gallery" (301), a capital little work, not free from manipulation in the window, where no sunbeam appears to enter, though the gallery and partition is flecked with sunlight. Another commended picture is the "Winter" of G. H. de Nagyrev (303), in which the middle distance is exquisitely given and the foreground admirably handled; the hard forms of the black trees, however, are a pictorial fault.

Coming now to the work of the local societies, a nice circular motive, caused by the "Bridge and Canal, Malines" (10), has inspired E. Welburn to produce a subject that gains him a certificate, to the honour of Aston. Bournville Camera Club takes one also with "Bruges" (16), by W. Davenport, whose tasteful mounting for something. Bournville and District has G. E. Mountford's "Meditation" commended. This shows a well-posed boy by an open door, looking out upon a river. It has feeling and a nice suggestion of planes. Brierley Hill's certificate goes to F. Gibbons for a very true and tender piece of work called "Floodtime" (38) wherein some sheep are quite remarkably well grouped. The bright area in the corner is a little awkward, but the atmosphere and fine tones. Erdington and Handsworth show work of such equal level that neither of them have one thing more noticeably good than the last. The King's Heath and Moseley Society are in the same boat. Neither, therefore, includes an award. The Municipal Technical School takes a medal and a certificate, the former for the charming "Roses" (75) of Lulu Hanman, a little red print of great taste and beauty, and the latter for an architectural piece called "Midst Massy Pillars" (71), by T. Fairfield. A certificate goes to E. Welburn, of Small Heath, for a peep through a Warwickshire courtyard, which appears to be wrongly named in the catalogue. It has excellent qualities of direct and reflected sunlight. Walsall, as a society, achieves a medal for the best work collectively, and G. W. Richmond personally takes another for his first-rate "Sister"—a Sister Mercy, by the way. This is very broad and simple in treatment, well-placed and trimmed, and with tones and textures perfectly ordered. A rather monotonous sky appears in the "Early Morning, Boulogne" (103) by W. J. Farthing, but it is the best of the Worcester group, and deserves its certificate for its nice composition. In the Colour Photography Section an unusually good and interesting collection of Autochromes distinguished this exhibition, and certificates fall to H. C. Holder for both an interior and a portrait, Nos. 25 and 26 respectively, and to W. Partridge for a "Flower Study" (14), whilst J. B. Walker gains a medal for his group work called "In a Conservatory" (52). Amongst the prints tiny and exquisite little group of "Corn Poppies" in a blue vase has been certificated. The thin and papery texture of the petals quite convincing. This is by S. Manners.

In the Lantern Slide Class, out of 148 slides two take medals, and five certificates.

The awards in the pictorial section were to have been made by Messrs. Furley Lewis, Mr. W. J. Wainwright, R.W.S., and A. Horsley Hinton, but owing to the illness—fatal, alas!—of the last-named, his place was taken by Mr. F. C. Tilney. The following is award list:—

**MEMBERS' SECTION.**—Bronze Medal: P. Bale Rider, No. 72, "The Shadow." Certificates: E. D. Taylor, No. 11, "Evening"; R. S. Clarkson, No. 19, "Portrait of Harold Baker"; H. W. Rennie, No. 37, "Hush-a-bye." Beginners' Section.—Certificate: A. E. Guytchard, No. 82, "Sunlight and Shadow."

**OPEN SECTION.**—Bronze Medals: E. O. Hoppé, No. 111, "Portrait"; J. Dudley Johnston, No. 220, "Snow in the City"; James Batkin, No. 223, "While the Daylight Lasts"; R. Dührkoop, No. 236, "Portrait of the Poetess"; J. C. Warburg, No. 263, "A Day Without Words." Certificates: A. E. King, No. 126, "Sun and Mist"; Mrs. G. A. Barton, No. 140, "The Fates"; E. T. Harding, No. 183, "Portrait: Miss Ethel McCarthey"; J. C. Warburg, No. 189, "The Wanderer's Return"; Heinrich Hinz, No. 201,

"Snow Landscape"; Mrs. E. Peake, No. 213, "Seeing the World"; R. Dührkoop, No. 235, "Conversation"; D. Murray, No. 280, "When Johnny Comes Marching Home." Hon. Mention.—H. Essenhigh Corke, No. 109, "Swarthy Cheeks and Bold Black Eyes"; Mrs. Mahony, No. 148, "A City Highway"; A. Benussi, No. 163, "Choigigia"; H. T. Winterhalder, No. 301, "Sunlight on the Minstrel Gallery"; George Haranghy de Nagyrev, No. 303, "Winter."

**LOCAL SOCIETIES' COMPETITION.**—Aston: Certificate, E. Welburn, No. 10, "Bridge and Canal, Malines." Bournville Camera Club: Certificate, W. Davenport, No. 16, "Bruges." Bournville and District: Hon. Mention, G. E. Mountford, No. 21, "Meditation." Brierley Hill: Certificate, F. Gibbons, No. 38, "Floodtime." Municipal Technical School: Medal, Lulu Hanman, No. 75, "Roses"; Certificate, T. Fairfield, No. 71, "Midst Massy Pillars." Small Heath: Certificate, E. Welburn, No. 84, "Mist and Rain." Walsall: Medal, G. W. Richmond, No. 97, "Sister." Worcester: Certificate, W. J. Farthing, No. 103, "Early Morning, Boulogne."

**COLOUR PHOTOGRAPHY.**—Autochromes: Medal, J. B. Walker, No. 52, "In a Conservatory"; Certificates, W. Partridge, No. 14, "Flower Study"; H. C. Holder, No. 25, "Interior," and No. 26, "Portrait." Colour Photography—Prints.—Certificate, S. Manners, No. 98, "Corn Poppies."

**LANTERN SLIDES.**—Medals: A. Roffey, No. 59, "The Vacant Tomb"; W. A. I. Hensler, No. 119, "Reflections." Certificates: Victor E. Morris, Nos. 7 to 10, "Street Scenes"; A. G. Thistleton, Nos. 17 to 20, "Figure Studies"; J. Dudley Johnston, No. 22, "In Salzburg"; Arthur Black, Nos. 80 to 83, "Flower Studies"; G. A. Booth, No. 96, "Thrush Study."

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were received between February 10 and 15:—

**ANIMATED PICTURES.**—No. 2,930. Apparatus for producing animated and panoramic effects in projected pictures. William Thomas Andrews, 22, Queen's Road, Leytonstone, Essex.

**PLATE-HOLDERS.**—No. 3,179. Improvements in photographic plate-holders. Optische Anstalt C. P. Goerz Aktiengesellschaft, 31, Bedford Street, Strand, London.

**COLOUR SCREENS.**—No. 3,252. Improved process for the production of three-colour screens for photography. John Bamber, 33, Cannon Street, London.

**CAMERAS.**—No. 3,303. Improvements in photographic cameras. William James Lancaster, 11, Burlington Chambers, New Street, Birmingham.

**PAPERS.**—No. 3,415. Improvements in photographic printing papers. George Wilson Morgan, 121, West George Street, Glasgow.

**CINEMATOGRAPHS.**—No. 3,458. Improvements in cinematograph pictures and apparatus for viewing the same. Theodore Brown and Bessie Kate Brown, 22, Gresham Road, Brixton, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**AGAR-COATED RAW PAPER.**—No. 2,155, 1907. The object of the invention is to provide an improved printing-out paper which shall be capable of being very cheaply produced. It consists in forming the surface upon which the medium, emulsion, or vehicle carrying the sensitive chemicals is to be deposited of agar-agar, which may or may not hold a baryta or like pigment. The agar-agar forms a coating directly on the paper basis, and the medium or vehicle carrying the sensitive chemicals is to be deposited upon this agar-agar coating or surface.

A paper is thus produced with a prepared surface on which is deposited the printing-out emulsion, this paper being much cheaper to produce and less variable than the so-called baryta papers of commerce, while the surface is "hard" and of a character suitable to the requirements of the manufacturer.

The agar-agar is not detrimental to the qualities or properties

of the emulsion. Moreover, when once it is set it is not dissolved in water until a temperature of about 98deg. C. is reached, though when once dissolved it remains liquid down to about 35deg. C.

The invention also consists in a printing-out paper consisting of a paper basis; an agar-agar coating on the paper basis, which agar-agar may or may not hold a baryta or like pigment; and a medium, emulsion, or vehicle carrying the chemicals sensitive to light deposited on said agar-agar coating.

In carrying the invention into effect according to one modification, an ordinary or low-grade paper, sized or unsized, is taken and coated with a weak solution of agar-agar, containing, say, from 1 to 2 per cent. of agar-agar. Baryta or other suitable pigment may be suspended in the agar-agar according to requirements. The paper is then dried and calendered. A surface is then obtained, either matt, polished or highly polished, as desired.

Some papers give good results when a solution of agar-agar is used without any pigment or with only extremely small quantities of pigment.

In some cases it is advisable to add borax or alcohol, or both combined. The effect of borax on the solution is peculiar, producing a "tackiness" or "stickiness" which is of advantage in the operation of coating. Borax has a further advantage of neutralising acids without being a base itself; this is accounted for by the fact that a higher acid combines with the sodium in the borax liberating what is termed boracic acid, which is such a weak acid as to scarcely justify that term, and certainly it is not harmful.

Alcohol has the effect of causing the emulsion to spread better and to decrease so-called "grease spots." It is found that agar-agar enables better surfaces to be obtained than can be done with animal sizing, and it can be worked more conveniently and rapidly than the latter.

After the paper has thus been provided with an agar-agar surface, the medium, emulsion, or vehicle—of whatever nature it may be—carrying the sensitive chemicals is put upon it in any convenient manner. William Francis Cooper, The Cooper Research Laboratory, Watford.

**CINEMATOGRAPHS.**—No. 14,056, 1907. The claim is for cinematograph mechanism, in which the feed-bath for giving an intermittent motion to the film is enclosed in an oil bath. Albert Urench, 50, Gray's Inn Road, London, W.C.

**REFLEX CAMERAS.**—No. 10,236, 1907. The invention is a reflex camera, the chief claim in reference to which is that it includes a shutter comprising two swinging superimposed plates normally

locked together and having coincident focussing apertures normally coincident with the lens opening, one of such plates having an additional aperture adapted, when the shutter is in the position it occupies immediately prior to making an exposure, to align itself with the lens opening so that when the other plate is allowed to swing relatively thereto exposure is made.

The specification requires the eight drawings to explain fully the construction. Lodewyk Jan Rutgers Holst, 1,410, President Street, Brooklyn, New York, and Louis Borsum, 955, Woodland Avenue, Plainfield, New Jersey.

**ASCERTAINING TIMES FOR EXPOSURE.**—No. 18,388. The apparatus consists of a compass placed in the centre of the base-plate, *a*. The axis on which the compass turns is also the axis of the disc *b* and *c*. Disc *b* is divided into five-hour divisions, Fig. 1, which correspond to five different solar positions, taken in a shade direction of an imaginary vertical bar in the centre of the disc. The divisions are calculated from the following solar positions:—

- + 23° 27' on June 21.
- + 11° 43' on April 20 and August 21.
- 0° on March 22 and September 23 (Equinox).
- 11° 43' on February 18 and October 23.
- 23° 27' on December 21.

Naturally the various hourly divisions can be arranged on different plates. In this case it would be necessary to discharge the plates detachable so that always the correct disc for the time of year could be in use.

Diametrically opposite the figure 12 is a pointer for adjusting the disc, *b*, with the division on the base-plate, *a*.

Fig. 1.

Fig. 2.

The disc, *c*, is so constructed that it covers the hour divisions on the disc, *b*, but not the words "forenoon" and "afternoon." The disc, *c*, is provided with a slit, *h*, so that the required hour divisions are visible, opposite a pointer, *e*, on the disc, *c*. Directly behind this pointer, *e*, is a photographic apparatus, at each side of which is an arrow, which arrows show the relative direction of the photographic apparatus to the object to be photographed. At both sides of the slit, *h*, are the months corresponding to the five solar positions so that the correct hour division can be quickly ascertained.

In order to ascertain the best time at which an object can be photographed, the apparatus is placed in a north-south direction; then the disc, *b*, is turned to the right or left (according to the required lighting angle), and then the disc, *c*, is turned until the two arrows point in the direction of the object to be photographed. The slit, *h*, then comes over an hour, with its corresponding month at which time it is best suitable for photographing the object. Alfred Muschke, 41, Grosse Bleiche, Mainz, Germany.

**MOLYBDIC EMULSIONS.**—No. 13,736, 1907. The process consists in treating organic substances, such as gelatine, albumen, or gums, with a solution of molybdic, tungstic, or uranic acid, or of compounds thereof, so that the mixture or the product of the reaction will show an excess of free (uncombined) acid. If neutralised solutions of such acids—i.e., solutions of the alkaline salts of such acids—are employed, acidification must be effected with hydrochloric acid or the like. Only preparations having an excess of acid show sufficient sensitiveness to light to be suitable for photographic purposes.

Preparations so made—if, for instance, applied to the surface of paper—yield a good "printing-out" paper—i.e., a paper giving a visible image in printing—which, for the purpose of obtaining permanent photographs after exposure to light, which produces at the exposed parts oxides that are coloured and not soluble in water, is treated with substances which transform that part of the

preparation which has not been acted upon by the light into a compound not soluble in water, and is then washed. Thus permanent copies or prints may be obtained from any negatives. Molybdcic acid or its compounds is or are most suitable; printing papers prepared with tungstic acid require to be fixed soon after exposure. The process is carried out as follows:—

Fresh albumenised or gelatinised paper is first saturated with gelatino-chloride in solution (produced by heating gelatine with dilute hydrochloric acid). The paper, having been drained, is floated upon a concentrated solution of molybdcic, tungstic, or uranic acid. For gelatine papers the treatment with molybdcic, tungstic or uranic acid alone will suffice, provided the gelatine is first permitted to swell in water. If, however, compounds of molybdcic, tungstic, or uranic acid having a neutral or alkaline reaction are used, then sufficient acid—hydrochloric, for instance—must be added to cause an excess of free acid. The manufacture may also be done by floating albumenised paper, firstly on a solution of gelatino-chloride and then upon a solution of metallic acid.

To produce permanent pictures, the prints are treated with a solution of barium or aluminium acetate, which will not affect the exposed parts, but will transform the unexposed parts into substances not soluble in water and not sensitive to light. The unexposed parts remain white, and therefore have no disturbing effect upon the image. The prints are then washed to take away any excess of barium or aluminium acetate. If, say, molybdenum paper is used, permanent prints in a blue tone from any suitable negative may be obtained. The pictures so produced may, if desired, be toned with gold or platinum. Johan de Ruiter, Bandveng, Java.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Metal Slides for Hand Cameras.

Personally (writes Mr. W. Thomas in "The Photographic News"), use, as occasion suggests, various forms of plate and film carriers, but the one most constantly in use, and giving me perfect satisfaction, is the single metal slide. It takes up little more room than the usual glass plate itself, and never seems to go wrong; but when such a rare accident does happen, if it is seriously damaged, the cost of a new slide is so trifling that the damaged slide may be discarded at once. Other reasons why I like the single metal slides are, that if by any chance they drop on to the ground, there is no risk of picking them up cracked and splintered, as might happen with wooden slides. Again, while they remain in working order, there need be no fear of their not being thoroughly light-tight, even when ultra-sensitive plates are enclosed. To mention but one other advantage—namely, the fact that pencil notes may be scribbled on the outside of these metal slides recording the particular kind of plate they contain at the moment—a very useful matter when using various kinds of plates.

## New Books.

Die Kinematographie: Wesen, Entstehung, und Ziele des lebenden Bildes." Von K. W. Wolf-Czapek. 8vo, 120 pp., 41 illustrated. Dresden, 1908. M. 2.50.

Brevity, no less than lucidity of expression, is to be commended. Both these qualities are apparent in this work, and it fulfils admirably the purpose for which it has been written, that of providing an account of the principles, origin, and uses of the living picture, which shall be clear even to those unacquainted with photography, and yet serve as a reliable handbook for those commencing the practice of the art.

Opening with a brief account of the nature of persistency of vision and the various apparatus used to demonstrate it, it proceeds to explain, very concisely, the optics and chemistry of photography, together with the manipulative processes necessary for the production of a photographic picture. To this follows a summary of the various early forms of living picture apparatus, thus including in the space of

36 pages an introduction which should give a very clear idea of the nature of living pictures to those who have not as yet ventured on the use of a hand camera.

The author does not attempt to describe the various types of machine on the market, but confines his attention to one alone, or at least the various forms of one make, the Ernemann "Kino," and especially the amateur model, which takes pictures 10 x 15 mm. on a film with central perforation. The practice of cinematography has always been, and of necessity must be, too expensive to become a general subject of amateur activity, and the introduction of small gauge apparatus, such as the "Biokam" and the "Kino," is the only means whereby expense may be reduced, and the taking of living pictures become a hobby in addition to a trade.

The most valuable section of the book is that dealing with the actual use of the apparatus and production of films. To this are devoted 26 pages, which give very clear directions for the production of both negatives and positives. Tables are given to show suitable stops and exposures for varying subjects and lights. The shutter of the "Kino" is formed of two sectors, sliding one over the other, thereby altering the area of the shutter, and, consequently, the exposure. The aperture of the shutter is expressed in the tables as millimetres, corresponding to a fraction of a second, and the tables are thus of general value.

A short description of the larger "Normal-Kino" machines is given, together with the accessories indispensable for work with ordinary gauge machines, and the whole concludes with a chapter on the varying uses of the cinematograph in art, science, technology, and education. The work, as mentioned, makes no claim to be regarded as an exhaustive treatise, but it certainly is so clearly written that all may understand, and it forms an admirable handbook for users of the "Kino," for which purpose it was apparently written. The section dealing with the actual taking of pictures is commendably practical, and anyone commencing the practice of cinematography would do well to peruse this little book, which, unfortunately, is only available in German.

H. V. HORWOOD.

"The Spectroscope and its Uses in General Analytical Chemistry.

By T. Thorne Baker. viii. and 130 pages, 8 x 5 in. London: Ballière, Tindall and Co. 5s. nett.

That the modern practice of analytical chemistry calls for a book of this kind may be readily admitted, and therefore in attempting to supply in the small space of a short manual such instruction as is necessary, the author has our commendation. Yet we are bound to question whether, in the sequel, the result justifies his qualification to pose as mentor to the professional chemist or the chemical student.

According to the author this work is to fill a felt want, and it is intended as an assistance for general chemical analysis. In the face of this one can hardly understand why accurate wave-lengths should not be given, as, for instance, in the table of the solar Fraunhofer lines on p. 54. Surely, in spectrum analysis extreme accuracy of the wave-lengths is all important.

Naturally the author dilates at length on the photographic side, but even here one meets with loose writing which may lead to trouble. For instance, he tells us that the measurement of the opacities of a negative in the blue and yellow-green will prove whether one light is richer in the latter colour than the former. A statement which, in the face of the researches of Eder, Stenger, Mees and Sheppard, and others, as to the difference in densities to different wave lengths, would appear to be far too wide.

Again, in order to determine photographically the composition of a substance by spectrum analysis, or, in other words, to determine the wave-length of an unknown line, the author recommends the photographing of a known line spectrum and then shifting the dark slide and photographing the unknown substance. This is absolutely valueless, for the one essential for accurate work is that there shall be absolutely no shift of any part of the apparatus, an absolute necessity when one considers that in such work one has to deal with ten-thousandths of a millimetre, sometimes to the third and fourth place in decimals.

It is curious to note that the author seems to be quite unaware of the existence of plane metallic gratings, and he perpetuates the old idea that a spectrum produced by a grating is always normal, although it is well known that it is not so. Far too many mathematical formulæ, without any explanation, are included, and

in one case, that of Hartmann's interpolation formula, one of the necessary constants is not defined.

**BRITISH BIRDS' NESTS.**—Messrs. Cassell are issuing this alphabetical work by Mr. Richard Kearton in 16 fortnightly parts, price 1s. each nett. The publication is fully illustrated by Mr. Cherry Kearton, and will contain a number of coloured plates of eggs. No. 1 includes a photogravure frontispiece.

## New Apparatus, &c.

The "Fulmenar" Anastigmat,  $f/6.8$ . Sold by O. Sichel and Co., 52, Bunhill Row, E.C.

This is an  $f/6.8$  Anastigmat, the focal length of the lens submitted to us being 7in., while the plate it is listed to cover is  $7 \times 5\frac{1}{2}$ . It appears to be of quite symmetrical construction, and if the front combination is removed the remaining back lens gives very good definition if stopped down a little. The complete doublet appears to be extremely well corrected as regards astigmatism, etc., and the lens, which is issued at a very moderate price, should satisfy many who require a good all-round anastigmat of not the very highest rapidity. Thus the  $4\frac{1}{2}$ in. lens is listed at £2 10s., and the 7in. at £3 12s. 6d. These prices are for brass mounts fitted with iris diaphragm.

## New Materials, &c.

**MOUNTS.**—The Crown Manufactory, Rotherham, send us some specimens of new series in mounts, which are deserving of commendation as distinctive in design and moderate in price. The "Oceana," a dark green mount at 5s. 6d. per 100 cabinets, is very neat, so is the "Melton," for ovals  $3\frac{1}{2}$  by  $5\frac{1}{2}$ , at 8s. 6d. A "Cosway," in lead-pencil grey, at 8s. 6d. per 100, is another tasteful style, and with several neat designs in circle mounts is listed in the Crown Co.'s new circular. The above prices in each case include printing of the photographer's name and postage.

**THE ANTINOUS RELEASE.**—Messrs. W. Watson and Sons, 313, High Holborn, London, W.C., have introduced an improved form of "Antinous" release for use on the Goerz "Sector" shutter. Instead of, as formerly, fitting on the nipple in place of the rubber tube, the nipple is unscrewed from the shutter and the release screwed in its

place. This gets over the difficulty sometimes experienced of attaching the release, owing to the shutter (in small cameras) working very close to the baseboard. The price of this release is 2s. 6d.

**Leto Plate-Markers.** Sold by the Leto Photo Materials Company, Ltd., 3, Rangoon Street, London, E.C.

The Leto Company in these additions to their series of specialties have certainly enhanced the effect obtainable on their "Boardoid" or extra-stout Seltona or other papers. The function of a printing paper of this weight is, of course, to obviate mounting, the negative being printed with a mask so as to give a clean margin to the picture. This margin can now be further improved by placing a plate-mark round the printed picture, for which purpose the Leto Company supply a piece of specially hard board so mounted that it registers with the print to be marked. The ordinary copying press, or, in its absence, the handle of a knife or other smooth surface, suffices to make the impression, and the result is unquestionably an improvement in the appearance of the print. Amateur photographers will be glad to have their attention drawn to the little device.

**"PAGET" COMPETITION.**—Mr. John Moffat, photographer, Princes Street, Edinburgh, has been awarded the first prize of £25 in the Paget competition for an enlarged portrait.

**CHANGE OF ADDRESS.**—Mr. George Faulkner, enlarger and trade worker, notifies us of his removal from Archway Road to larger premises, at 44, Finchley Road, Upper Holloway, London, N.

## CATALOGUES AND TRADE NOTICES.

**FALLOWFIELD'S BARGAIN SALE.**—Two lists, one of mounts and the other of general apparatus, have been issued by the firm of Fallowfield in connection with its annual stock-taking sale. Our advertisement pages give evidence of some few of the bargains to be picked up, but the two catalogues should be obtained for a proper apprehension of the very large variety of goods offered at, roughly, half price. The list includes plates and papers, cameras and lenses, shutters, finders, camera stands, dishes and tanks, washers and dark-room lamps, and a variety of photo-button apparatus. The stock of mounts to be disposed of at the reduced prices evidently runs into many thousands, and it would seem that 146, Charing Cross Road, where the articles can be seen, will be besieged by photographers during the three weeks of the sale. Yet country buyers should note that Messrs. Fallowfield have arranged to send fuller particulars of any items from the list on application being made to them.

**THE CATALOGUE** of the stocktaking sale at Houghtons Ltd., which has now reached us, is found to include in its twenty pages a large number of bargains in box, folding, and field cameras, lenses and shutters, and many varieties of mounts and albums. The demand for these bargains is usually such that immediate application to 88-89, High Holborn, is desirable.

**WRATTEN PLATES.**—The new list of Messrs. Wratten and Wainwright is now only a price list—not as previously, something of a text book. As a price list it gains by the change, and for the technical information which Messrs. Wratten pride themselves on holding at their customers' disposal, there are seven distinct booklets to be had for the asking. Any or all are sent free from Croydon.

**HAND AND STAND CAMERAS.**—Mr. L. Gandolfi, as a maker of cameras, has our respect, and we are therefore glad to find he has published a small list of the apparatus to the manufacture of which, as we know, he devotes the most careful personal supervision. The chief item in the list is the description of the "Universal" hand-stand camera. The six drawings on page 3, which illustrates its great range of movements, are deserving of study by those seeking a good deal in a folding camera. The list is posted free on application to 752, Old Kent Road, London, S.E.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, FEBRUARY 28.

Waltham Dearne Photographic Society. Rotary Carbohydrate Paper.  
Cardiff Photographic Society. Pontypool Photographic Society's Slides.  
Sutton Photographic Society. Members' Excursion Slides.

MONDAY, MARCH 2.

Harrow District Photographic and Scientific Society. "Photo-Chemistry." W. A. Luty, A.R.C.S.  
Cleveland Camera Club. Amateur Photographer Prize Slides.  
Bradford Photographic Society. Members' Slides.  
Southampton Camera Club. Focus Prize Slides.  
Catford and Forest Hill Photographic Society. "Finishing a Print for Exhibition."  
Rev. H. O. Fenton.  
Kidderminster and District Photographic Society. Members' Lantern Slides.  
Bowes Park and District Photographic Society. "The Ancient Churches of South Essex." C. Forbes.  
Scarborough and District Photographic Society. "Here and There, at Home and Abroad." J. H. Rowntree.  
Lancaster Photographic Society. Demonstration by B. J. Edwards & Co.  
South Manchester Photographic Society. Discussion on the Exhibition.  
Workington Photographic Society. "Enlarged Negatives on Rotograph Negative Paper."

TUESDAY, MARCH 3.

Royal Photographic Society. "The Autochrome Plate applied to Natural Science." By F. Martin Duncan.  
Epsom and District Literary and Scientific Society. "Platinotype." Platinotype Co.  
Hanley Photographic Society. Members' Night. Mr. Outlack.  
Worthing Camera Club. "Sussex Highways and Byeways." R. J. MacDermott.  
Stafford Photographic Society. "Finishing P.O.P. and Self-Toning Prints." C. E. Fowke.  
Redhill and District Camera Club. "A Visit to English Cathedrals." H. W. Bennett.  
Sheffield Photographic Society. "The Sheffield Parish Church." James H. Wigfull, A.R.I.B.A.  
Wishaw Photographic Association. "Enlarged Negatives on Rotograph Negative Paper."

WEDNESDAY, MARCH 4.

Croydon Camera Club. "Photo-microscopy with Simple Apparatus." J. Bawcomb.

th Suburban Photographic Society. "Photography at the Royal Observatory, Greenwich." E. W. Munn, F.R.A.S.  
 Ingham Photographic Society. "Advances in Colour Photography." J. Tudor Cundall, B.Sc.  
 rough Polytechnic Photographic Society. "A Ramble in London with Charles Dickens." Miss M. Smith.  
 Middlesex Photographic Society. Lantern Slide and Print Competitions. Camera Club. "Wells; Its Cathedral and Neighbourhood." A. E. Hasse.  
 istol Photographic Club. "Rambles along the Chew." W. F. Kuner.  
 st Calder Camera Club. "Enlarged Negatives on Rotograph Negative Paper."

THURSDAY, MARCH 5:

elsea and District Photographic Society. "Shanklin." L. Hill-Bailey  
 "North Devon." C. Cutts.  
 herham Photographic Society. "A Trip to Belgium." J. W. Wright.  
 C. School of Photo-Engraving and Lithography. "The Production of  
 Intaglio Plates." A. E. Bawtree.  
 rhmond Camera Club. Competition Prints.  
 ll Photographic Society. "Ozobrome Process." F. W. Doughty.  
 ckney Photographic Society. Annual Meeting.  
 gby Photographic Society. "The Pinatype Process as Applied to Three-  
 Colour Work." E. E. Wedmore.  
 ll Camera Club. Debate. W. Swindon and Mr. Stollwood.  
 asgow Southern Photographic Society. Rotary Carbohydrate Paper.  
 mbridge Wells Amateur Photographic Association. "Some Rarer Marsh Birds."  
 Miss Turner.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, February 25, Mr. John Sterry in the chair. Paper was read by Mr. K. J. Tarrant on "Photography as an aid to Electrical Research," in which the author described the photographic records of discharges of high tension of electricity, and showed the examples he had been able to produce of artificial thunderstorms on a small scale in the laboratory. The graphic representation of a lightning flash descending upon a series of miniature buildings proved of considerable interest. The lecturer also exhibited a number of Autochrome photographs of Geisler, Crookes, and other tubes when in action. These he had made with the help of Mr. J. McIntosh, and the results proved the usefulness of the Autochrome plate in work of this kind.

CENTRAL TECHNICAL COLLEGE PHOTOGRAPHIC SOCIETY.—A meeting held February 19, Professor Ashcroft in the chair. Mr. Rogers, of Messrs. Fuerst Bros., gave a lecture and demonstration of the "Pinatype" process of colour photography.

CROYDON CAMERA CLUB.—The seating capacity of the club-rooms is severely taxed last week, when Dr. Mees lectured on "Colour-reen Plates." The lecture, which mainly consisted of a condensation and simplification of a paper recently read at the Society of Arts, very clearly explained the broad principles underlying colour-ography in general, and screen-plates in particular, and was illustrated by a series of unique slides. Perhaps of all the screens of mosaic plates shown, that of Krayn aroused the greatest interest, possibly owing to its ingenious method of manufacture. A most hearty vote of thanks was accorded Dr. Mees, and to Mr. S. Wratten and Mr. Pledge for kindly assisting.

HULL PHOTOGRAPHIC SOCIETY.—Mr. W. F. Slater lectured last Tuesday on "Time Development." In going through the theory and practice of this subject it was made clear that, given a fairly correct exposure to the plate or film, the question of development is nothing short of a mechanical process. This was proved by developing a spool of film in the Kodak daylight tank, the exposures covering such subjects as portraiture, interiors, landscapes, etc., with a wide latitude in tone values, yet every one of them came out very well indeed.

In illustration of the difference between the expense of films and plates, the lecturer said: Suppose one takes 12 dozen plates on a holiday tour; they will cost 15s. backed, or a saving of 21s. on films. The plates will take 36 hours, at the very least, to develop and fix, as against six hours on films developed in lengths 12 at a time. The question of facing three and a half full working trays in the dark-room has to take first consideration, and how any one could go through such a labour when the simple method of daylight developing was at disposal he failed to understand. Thirty hours at 8½d. per hour comes to £1 1s. 5d., whilst there was no gain as regards health and eyesight. The lecturer's suggestion was that the time saved could be most profitably devoted to the operation of the print or more consideration given to your work at the exhibition.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Meeting held January 20, Mr. O. S. Dawson in the chair. Mr. Archer Clarke lectured upon a modern photo-mechanical process, or, as

he preferred to term it, the missing link between photography and lithography. This, he stated, was a means whereby a greasy image could be printed direct on to the litho' stone or meta' plate from the original if the same scale was required, or from a reversed negative for reduced work. The process of making transfers by the bichromate method was touched upon, and it was stated that there was much waste of paper when using this means owing to the fact that it had to be sensitised overnight and would not keep. He then introduced a new method of working in the shape of "amphitype" paper. This paper, he said, will keep indefinitely if stored from light and damp, so that the operator had only to cut from his roll the quantity required. Many examples of work done by its aid were passed round, and the following took part in the discussion:—Messrs. Butterfield, Dawson, Beckett, Rapson, Stretton, and Haddon.

## Commercial & Legal Intelligence.

A PLATINOTYPE DISPUTE.—In the Wood Green County Court last week Walter Edward Dalglish, photographer, of Newton Avenue, New Southgate, sued J. Hayes, stationer, of "Glenholm," Sidney Avenue, Bowes Park, for £3 15s. 9d., in respect of photographs taken and supplied to defendant's order.

Mr. G. H. Rittner was counsel for plaintiff. Mr. W. P. Armstrong, solicitor, represented defendant.

Plaintiff said that on September 18 last he received a postcard from defendant asking him to take a photograph of his family. This he did on the following Sunday, and subsequently sent on proofs to defendant. At defendant's request the photographs were executed in the platinotype process, and on delivery both defendant and his wife spoke well of them. No complaint was made until November 23, when defendant wrote saying he was very disappointed with the photographs, and he was sorry to have to reject them.

In the same letter defendant said that he could not send the photographs to his friends, as he was afraid they would inquire who was represented.

A number of the photographs were produced in Court.

His Honour, Judge Edge, in regard to the question of likeness, described the photographs as easily recognisable as the defendant. He remarked to one witness who explained why less detail appeared in one process of photography than in another, "You are talking to a photographer, and one who has been a photographer for fifty odd years."

The Judge, in giving his decision, said the platinotypes were certainly not what he should call first-class, but there was no representation that they would be first-class or high-class, and a first-class price was not charged. But, although low, he thought the charge was in excess of what the goods were worth, and he should reduce the claim.

It was stated that three dozen and nine photographs were supplied.

The Judge: I have taken 6d. off each. There will be judgment for plaintiff for £2 11s. 3d. and costs.

AN UNPROFITABLE BUSINESS.—Before Mr. Registrar Giffard a sitting was held for the public examination of Herbert Dawson, from whose statements it appeared that in 1899 he, with £1,600 capital, of which £1,000 had been borrowed, commenced, and until the date of the receiving order carried on, business as an advertising contractor at Norfolk Street, Strand, W.C., under the style of H. Dawson and Co. For the past seven years he had also traded as a manufacturer of photographic apparatus at Wimbledon in partnership with another person. The receiving order was made upon the petition of Mr. A. F. Walter, of the "Times," Printing House Square, E.C., and the debtor has furnished a statement of affairs disclosing gross liabilities £28,626 12s. 9d., of which £25,247 18s. 5d. are returned as unsecured, and an estimated surplus in assets of £4,698 19s. 10d. On examination the debtor said that he had built up a turnover in his business of over £40,000 a year, but latterly the profits had fallen away. He had also given his time to a camera business, and to several company matters, with the view of obtaining orders for advertisements. The examination was concluded.

A SOUTH WALES BANKRUPTCY.—A meeting of creditors of Sidney and Josiah Butt, 75, Trebonal Road, Skewen, near Neath, Glam.,

photographers, etc., was to be held at Swansea on February 19. No creditors, however, put in an appearance, and the Official Receiver (Mr. Thomas Thomas) remains trustee. The gross liabilities are placed at £62; expected to rank, £52; assets, after meeting preference claims, which amount to £8, nil. The cause of the failure is ascribed to bad trade.

**MANUFACTURER'S FAILURE IN BIRMINGHAM.**—In the Birmingham Court of Bankruptcy last week Mr. Registrar Lowe made a receiving order in the matter of John Page Croft, of Packwood, Grove Avenue, Moseley, and carrying on business at Cooksey Road, Small Heath, photographic paper and apparatus maker, and also at 24, Quadrant Chambers, New Street, Birmingham, tea merchant. Messrs. T. W. Walthall and Pritchard are solicitors in the proceedings.

**FORDHAM AND CO., LTD.** (Photographic Mount Manufacturers, Walthamstow).—Issue on January 14 of £1,000 6 per cent. debentures, part of series created March 26, 1906, to secure £6,000, charged on the company's undertaking and property, present and future. Holder, G. Miller, Surrey House, Victoria Embankment, W.C. No trustees. Total amount previously issued of same series, £5,000.

**CHARGE AGAINST A CANVASSER.**—James Smith Dickie, a travelling photographer, was convicted at Arbroath last week of having, on various dates in January and February, fraudulently obtained photographic articles to the value of £1 13s. 2d. A fine of £2, with the option of thirty days' imprisonment, was imposed.

**H. BOWN (LIMITED) v. HENRY BOWN.**—Judgment was given last week in this action, brought by a company formed to take over the defendant's business of a photographic artist, for specific performance of a contract to sell it for £10,000. The facts, which were reported in "The Times" of Wednesday, showed that the contract sued on and an earlier one were obtained by the fraudulent misrepresentations of Thomas Isaac Grimes, who became managing director of the company. The case stood over for the defendant to consider what judgment he should ask for on his counterclaim, which was, alternatively, for rescission of the contracts or for payment of £5,000, the cash portion of the purchase money, and of £1,500, paid by him to Grimes.

Mr. Astbury, K.C., and Mr. G. F. Hart, for the defendant, now submitted minutes, to which, with some modification, Mr. Frank Russell, K.C., and Mr. Laurence Rostron, for the company, agreed.

Mr. Justice Swinfen Eady gave judgment dismissing the action, with costs, declaring that the agreements of November 23, 1906, and January 7, 1907, were obtained by the fraud of Grimes, and ordering them to be set aside and rescinded. He ordered possession of the business and of the properties referred to in the agreements to be delivered to Bown and deeds and documents, books, and papers relating to them to be handed over, with all the assets of the business, except additional premises acquired since November 23, 1906. The debentures and shares received by Bown were to be handed back, and there was judgment against Grimes for £1,500 and £500, and against him and the company for costs of the counterclaim. The receiver who had been appointed pending the action was to be discharged, and there was liberty to apply as to his remuneration and as to any balance due to or from him, and also (without prejudice to any question) as to any outstanding liability in respect of debts incurred by the company while carrying on the business.

**PICTURE POSTCARDS IN COURT.**—At the Clerkenwell County-court, on Monday last, before his Honour Judge Edge, the British Art Company, photographic printers, of 61, Essex Road, Islington, sued Felix McGlennon, music and postcard publisher, of Bouverie Street, E.C., for £25 4s. in respect of work done. Mr. Dodd was counsel for the plaintiff, and Mr. O'Gorman for defendant. In opening the case, Mr. Dodd said that Mr. McGlennon conceived the idea of having a series of postcards printed, illustrating the poem by Geo. R. Sims, "Christmas Day in the Workhouse." Plaintiffs were given an order for a series of twelve photographs, 1,000 of each. The order was delivered in December, 1906, but, as Mr. McGlennon made a complaint that they were not fit for sale, plaintiffs undertook to print further editions. This they did, and duly delivered the cards. He (counsel) understood that the defence alleged the cards to be of an unmerchantable quality.

Alexander Simmon, of the plaintiff firm, said the cards were merchantable. Proofs were submitted to Mr. McGlennon before the

bulk was printed. Witness never admitted that the cards were unsealable.

Some of the cards were handed up to his Honour.

An expert, giving evidence as to the merchantable quality of the goods, said it was possible to remove some of the marks from cards. It was not possible, added witness, to get absolute uniformity of tone in photographic prints. Another expert corroborated this statement.

Questioned by counsel as to the difference in cards handed up, witness said that some people liked them brown, and some preferred a darker photograph. Are these the same in tone?—No one would guarantee that they would be exactly the same in tone.

Referring to certain markings, witness was asked if purchasers of picture postcards would be likely to raise an objection?—It just depends on the purchaser. Some would notice it; others would not.

Mr. Price, defendant's manager, said that if he offered the cards in question to the wholesale trade, they would be refused on account of the dirty marks and the variability of the tone. The great objection was the dirtiness where the letterpress ran.

Had the marking been treated before fixing, said an expert, they could have been removed.

Mr. Dodd: I put it to you that it cannot be done until after the photograph has been finished?—I say it can be done.

Another witness in the trade said it was part of the operation to remove the abrasion marks before the photographs were sent out.

The darker tone was said to be the most popular on the market now.

The brown tone was known as "gingery" in the trade.

Having examined a number of cards, the Judge thought the defendant was rather hypercritical in saying or supposing that they were not reasonably merchantable. There were some bad ones, and he thought some deduction ought to be made from plaintiff's account. He thought £2 2s. would be a reasonable sum to allow, and the verdict would be in plaintiff's favour for £23 2s. and costs.

## News and Notes.

**DEATH OF A PHOTOGRAPHER.**—The death took place in Glasgow last week of Mr. John Fergus, who died as the result of an accident which befell him the previous day. The deceased was well known in Scotland as a photographer. His studio at Blackdales, Largs (a mansion-house which he purchased about thirty years ago, ten years after he started as a photographer in Largs), was famous all over the West of Scotland, most of whose notabilities a quarter of a century ago were photographed there. Deceased had also a studio at Cannes, in the French Riviera, where he photographed many crowned heads and illustrious persons, including the King when he was Prince of Wales, and the late Mr. Gladstone and his wife.

**STEREOPHOTOGRAPHIC SURVEYING.**—At a meeting of the research department of the Royal Geographical Society, held on February 21 and reported in the "Times" for February 22, Lieutenant E. Vivian Thompson, R.E., read a paper on stereophotographic surveying. He described the method as consisting of taking photographs in pairs, in the same vertical plane, at a measured distance apart, and viewing the negatives or positive transparencies obtained from them in a special form of stereoscope. The eye-pieces of the stereoscope were provided with exactly similar indices, which could be made to combine stereoscopically with any given point in the view by increasing or decreasing the distance between the slides holding the photographs. The amount of separation required for stereoscopic combination was a measure of the range of the point from the plane in which the plates were exposed, and could be read on a suitable scale. Azimuth and elevation or depression could also be read from scales on the instrument. Thus any desired point on the view was completely fixed. By using a long base line, say 100 yards, a very exaggerated stereoscopic or relief effect was obtained, so that a fold in the ground at ranges up to five or six miles was easily perceptible. The effect was what would be seen by a person whose eyes were 100 yards apart, and was 1,440 times the relief effect seen by normal eyes which were 2½ in. apart. In plotting the observations on the map, it was desirable to keep pace with the camera party—that was, to fix in plan and altitude from 500 to 2,000

ints a day. With a view of making this rate of plotting possible, the reader of the paper had designed a "stereo-plotter," which was development of the Pulfrich "stereo-comparator," and made the setting of points and the reading of heights partially automatic. The Pulfrich instrument the data for plotting were obtained from three Vernier readings for azimuth, elevation or depression, and parallax, corresponding settings being made on a detached plotting-board. In the stereo-plotter the binocular microscope and the negative slides were similar to those of the stereo-comparator, but the motion of the slides, instead of being measured by scales, was transmitted direct to the plotting-board, which formed part of the instrument. By this means the three readings and settings of the stereo-comparator were reduced to a single reading on a drum graduated in yards and one setting.

**A SOCIETY FOR CHISLEHURST.**—A photographic society has recently been formed for Chislehurst and its neighbourhood. Suitable premises have been secured, where meetings will take place fortnightly during seven months in the year. The president is the Rev. James E. Dawson; Dr. Allan and Mr. F. A. Robinson are vice-presidents; Mr. A. Saalfeld is hon. treasurer; and the committee of ladies and gentlemen contain the names of Miss Dawson, Miss Robinson, Miss Fletcher, and Messrs. E. De Quincey and A. J. Gordon. The hon. secretary is Mr. G. W. Miller, of The White House, Chislehurst, who will give any further information on the subject intending members.

**THE BIRMINGHAM PHOTOGRAPHIC COMPANY** writes: "Your readers may be interested to know that our premises were broken into by burglars on Monday of last week, and the whole of the place ransacked from top to bottom. Unfortunately, an entry was made through our bromide emulsion setting-down-room window, which, of course, was blocked up at the time. We happened to have a full stock of bromide, as well as a number of tests, down at the time, and, of course, the whole of these were spoilt. However, our stock is sufficient to enable us to execute all orders by return of post as usual. Some cash and cheques were stolen, but our photographic records appear to have been too heavy and bulky to have been taken away."

**MALVERN CAMERA CLUB.**—The annual exhibition will be held in the lecture hall of the Public Library, Malvern, from March 30 to April 4. There will be three classes, open to all photographers, in each of which a bronze plaque, medal, and certificate will be placed at the disposal of the judge, Mr. Arthur Marshall, F.R.P.S. Entries close on March 21, and exhibits must be delivered, carriage paid, at the Public Library, on March 26. Entry forms and full particulars may be obtained from the secretary, Mr. J. B. Nickolls, The Range, Malvern.

**LECTURES AT THE BOLT COURT SCHOOL.**—Three short courses of lectures, which should prove of interest to those engaged in any of the crafts concerned with illustration—in photography, and book design, or newspaper production—will be given at the L.C.C. School of Photo-Engraving and Lithography, 6, Bolt Court, Fleet Street, E.C.4, on Thursday evenings during the months of March, April, May, and June. From March 19 to April 2 Mr. James Black, manager of the plate-making department of Messrs. Spottiswoode and will give three lectures on "Duplicate Plate-Making," dealing fully with the processes of stereotyping and electrotyping, including finishing methods and the application of machinery. From April 14 to 28 Mr. R. W. Sindall, F.C.S., will give three lectures on "Papers for Printing," in which he will deal with high-class, half-tone, and half-tone printing, and the suitability of the various papers of paper to each, the characteristics of the various papers, manufacture, etc. The third and last course will be given by Dr. S. E. Sheppard, from June 4 to 25, who, in the course of his lectures, will deal with "The Chemistry and Physics of Colloids," in their relation to photographic and photo-mechanical processes, based on the nature and characteristics of colloids; reversible and irreversible colloids; preparation and analysis; jellification and coagulation; methods of investigation; ultramicroscopy; and its relation to colloidal phenomena; absorption of inks, etc.; absorption and solid solution. The above lectures are free for students of the school, but a small fee of 2s. per course is charged for non-students. Tickets for all or any of the lectures may be obtained from the school.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

### SULPHIDE TONING OF BROMIDE PRINTS.

To the Editors.

Gentlemen,—I notice that from what you say in your leader and from what has appeared in other journals, there still is much misapprehension about sulphide toning. Some three or four years ago I very carefully tested this method, and my conclusions were, as I dare say you know, published in various articles contributed to "Photography." There has been lately a good deal of nonsense written about this subject. It was therefore very refreshing to see Mr. Munkman's article in the last edition of your paper. This article confirms my own work on the subject. Long ago I maintained in "Photography" that when all solvent action is avoided "the tone finally obtained is a function solely of the original silver image." There seem to be two main sources of error into which a good many people have apparently fallen:—

- (1) The use of an improperly made-up bleacher.
- (2) The use of impure sodium sulphide.

I have emphasised the importance of these two points often enough, but apparently my warnings have not been heeded.

Of course, if the bleaching solution either adds some foreign substance to the image, as in the case of certain bichromate-chloride bleachers, or if it has a solvent action on the image, as in the case of the ammonia-ferricyanide one, an alteration in the tone is brought about.

If, however, additive and solvent actions are avoided it makes no difference whatever whether the image is bleached to chloride, bromide, or iodide. I tested this point very carefully, and I am glad to see Mr. Munkman confirms my view. When I first commenced to experiment on sulphide toning the only reliable bleacher known, which it was possible to use, was the iodine one. The ferricyanide-bromide bleacher was not known, and nobody had published a reliable bichromate-chloride one. Thus it was that I at first always strongly advocated the use of iodine. Now, however, that other good bleachers are available the use of iodine has rightly ceased almost entirely. It is certainly the fact that an iodine bleacher is more bother to use than many others. The ferricyanide-bromide bleacher was, I believe, first brought forwards by Mr. Edwards, and a really reliable bichromate-chloride one by myself. The principles of the latter solution were first explained by Messrs. Piper and Carnegie.

Nobody who uses sodium sulphide should use anything but the best quality. I have always insisted on this point. I advise that only the pure analytical reagent ( $\text{Na}_2\text{S} \cdot 9\text{H}_2\text{O}$ ) be used. There are the following varieties of sodium sulphide at present on the market:—

- (1) Fused sodium sulphide ( $\text{Na}_2\text{S}$ ).
- (2) Crystalline sodium sulphide ( $\text{Na}_2\text{S} \cdot 9\text{H}_2\text{O}$ ).
- (3) Crystalline sodium sulphide ( $\text{Na}_2\text{S} \cdot 9\text{H}_2\text{O}$ ) "purified for analysis."

The latter (No. 3) only is the one to be used. I always buy my sodium sulphide from Messrs. Baird and Tatlock, of 14, Cross Street, Hatton Garden, E.C.

One can now get the sulphide practically free from iron, and so no boiling is necessary.

I advise photographers only to buy fairly small quantities at a time, and to make up all of what they buy into a stock solution at once. Say one buys 1 lb. of sodium sulphide, this should be dissolved in about ten ounces of water, and then the solution should be made up to sixteen ounces with more water. It is important that the stock solution should be strong, as it keeps best thus. I advise that the stock solution should be kept in a stoppered bottle, the stopper of which is greased with a little vaseline or other hydrocarbon grease. If much stock solution is stored it is as well to have a small bottle of about 5-oz. capacity which is kept filled from the main store, and to take out the solution actually used for making up the toning bath from this small bottle.

I have kept a 20 per cent. solution of sodium sulphide for a year or more without apparent deterioration. There is absolutely no

difficulty presented here if ordinary care is used. The actual toning bath is made up by taking

Stock sulphide solution .....  $\frac{1}{2}$  oz.  
Water ..... 4 to 7 oz.

The contamination of the sodium sulphide, when it occurs, is caused by oxidation. The substance is acted on by the oxygen of the air thus:—

Sodium thiosulphate ("hypo") being finally formed. I have tested the effect of adding "hypo" to the toning bath, and I find that it is possible to add  $\frac{1}{2}$  per cent. of "hypo" to a 1 per cent. solution of  $\text{Na}_2\text{S}_9\text{H}_4\text{O}$ , without effecting the tone of a bromide-bleached print, but that  $\frac{1}{2}$  per cent. of "hypo" made a difference which was just perceptible, and 1 per cent. an easily perceptible one. In the case of a chloride-bleached print the differences are, as one would expect, more marked,  $\frac{1}{2}$  per cent. "hypo" in the toning bath here shows itself quite plainly, although certainly not strikingly. Here, then, is the reason why some have always maintained that chloride-bleached prints give a different result to bromide-bleached ones—the experimenters used impure sodium sulphide. It should be noted that in the actual case of any of the sulphide being oxidised to "hypo" its strength is naturally reduced. In order to counteract the effect of slight impurity it is perhaps advisable never to use the toning bath of a less concentration than 1 per cent. or so—although with an absolutely pure sulphide solution the concentration has no bearing on the tone obtained. This I pointed out long ago in "Photography." In your note you mention the differences noticed in certain brands of paper. It is possible with some papers to get images which appear all right in every way in the "silver" stage, but which do not yield a very good colour when sulphuretted. The reason of this, I believe, is as follows:—All "silver" images are really halide "lakes." The black images to which I am now referring, of course, contain only a very little halide. Some black "silver" images, however, contain a fair amount of silver halide, and these, as in the case of "re-developed" images, do not yield on sulphuration an image of the same tone and depth as would be expected by a visual examination of the original "silver" image. Since here in the case of black "silver" images the halide is only present in very small quantity we can look upon it as dissolved in the metallic silver. This is a subject I want to look further into. I need not point out that such a phenomenon in no way contradicts the great general principle underlying the sulphide toning process, but that the tone is a function solely of the original silver image. It only shows that we cannot tell the nature of an image by merely looking at it, unless we have had a lot of experience, and not always then.—Yours truly,

31, St. John's Road, Putney, S.W.

R. S. BLAKE SMITH.

February 21, 1908.

P.S.—Possibly some of the differences noticed in the action of thiomolybdate and the thioannate are due to the fact that these substances yield lakes, whereas  $\text{Na}_2\text{S}$  yields silver sulphide. If so, this is to the credit of  $\text{Na}_2\text{S}$ .—R. S. B. S.

#### SEPIA-PLATINUM PAPER.

To the Editors.

Gentlemen,—I was very pleased to see the letter referring to sepia-platinum paper in your journal of the 14th inst. I may say that I have always been doubtful in regard to the permanence of such prints, and although I have practised the platinum process since 1886, I have never tried any but the black paper on that account. However, now that I see the Platinotype Co.'s paper has stood the test mentioned, I propose giving it a trial. I mean, of course, the "Japine" paper, and shall esteem any remarks you may be able to offer, in addition to what has been said.

As regards developing, separate dishes will, of course, be used, but would you kindly say if separate dishes should be kept for fixing? I do not mean to fix the different kind of paper at the same time, but after well cleaning, would it be safe to use them for the fixing of black prints afterwards?

I should not like the purity of the blacks to be at all affected.—Yours, etc.,

W. J. BARKER.

14, Victoria Mount, Leeds.

February 22, 1908.

[If the dishes are well cleaned there can, of course, be no trouble.—Eds. "B.J."]

#### DRYING NEGATIVES WITH SPIRIT.

To the Editors.

Gentlemen,—On page 18 (1908) of your esteemed weekly you state that you have not seen any satisfactory explanation of the formation of white opalescent stains (films) while using methylated alcohol for drying negatives. I beg you to allow me to say that the well-known chemist, Dr. Lüpke-Cramer, on page 73 of the "Photographischer Rundschau" (1907) has given, as I think, a satisfying explanation of the stain above named. He found that gelatine containing some water has a honeycomb-like structure, which cannot be detected under normal conditions, but it appears as if the gelatine is coagulated in alcohol, in which case the difference is heightened between the refractive power of the walls of the cellulose and their content. By re-soaking the gelatine the difference is destroyed and the structure disappears.—Yours faithfully,

K. W. WOLF-CZAPKE.

Dresden-A. 21.

February 17, 1908.

#### PINHOLE APERTURE NUMBERS.

To the Editors.

Gentlemen,—The object of my letter of December 20, to which Dr. Power replies, was to point out that the whole of the credit of the Watkins-Power table, published in the last issue of the "British Journal Almanac," and taken from the "Watkins Manual," was due to Dr. Power. I had not seen either "Camera Craft" or the "Photo-Miniature" containing Dr. Power's tables, and my own knowledge of his plan was taken from a short article in "Photography," June 11, 1904. Now that I have seen No. 70 of the "Photo-Miniature" let me say that the table there given is entirely different in standards and relative sizes from that which I devised from my own standards, and called the Watkins-Power table.

I deny emphatically the statement made twice in the "Photo-Miniature" that I have adopted Dr. Power's method and standards. My table is from my own standards, and was given from 1895 onwards in the third, fourth, and fifth editions of "Exposure Notes" and in the early editions of the "Watkins Manual." The present modified form I called the Watkins-Power table, because I wished to give the fullest acknowledgment of the fact that an idea in naming the apertures had been taken from Dr. Power.

Dr. Power mentions that he does not think "the relation of seconds to minutes is the important part of my formula." He is wrong here, for if the plan (devised by me and perhaps re-invented by him) of naming the apertures as if they were 60 times their true exposure value, is eliminated from his system, it would lose all its value, the diaphragm sizes would be far smaller than those marked on camera or exposure tables. For example, his No. 3 at 10 inches would have to be calculated as  $f/240$  instead of  $f/30$ .

Dr. Power corrects my statement that his No. 4 is  $f/32$ . I am obliged to him for the correction, but I took the information from the article in "Photography," and it is there fully explained why  $f/32$  is called No. 4, and there is evidently no misprint. His present table is entirely different from his first one. No. 4 is also given as  $f/32$  in the latest "British Journal Almanac."

But according to Mr. Douglas Carnegie, none of the tables under discussion are of any value, as light through pinholes does not follow the usual rules applicable to lenses.

ALFRED WATKINS.

Hereford.

February 22, 1908.

#### PHOTOGRAPHERS AS PROFESSIONAL MEN.

To the Editors.

Gentlemen,—Having watched with interest, too intense for words, the glorious evolution (on paper) of the coming university-graduate professional photographer, even to have him protected and licensed (like a public house), it seems inconclusive to close this discussion without fixing up a distinct type, so that all who run read—read and run afterwards?

For instance, when you see on the stage a man attired in a smooth red hair, and a huge spotted handkerchief twisted round his neck, you know he is a countryman, though you see his like nowhere else, likewise the stage doctor, lawyer, butler, "buttons," and other great lights, but where shines the stage artist photographer?

Greatly daring, might I humbly suggest that a Grand Committee of High School experts sit, *in camera*, and decide upon the "department"—à la Mr. Turveydrop—and personal furnishings of this coming

splendid studio accessory—I beg his pardon! acquisition, please, Mr. Printer.

In the faintest whisper might one propose that the indelible hall mark of exquisite perfection be stamped upon this ethereal type by his hair and accent—say hair six or eight inches long, waved, and parted down the middle. Accent, that of the budding curate of the deep-toned Gothic variety, coming somewhere from the region of his "dicky"—bother! these cheap fountain pens always get the wrong word—I mean his short buttons, jewelled in every hole.

Should he glare one eye, or wear a lens cap in it? His lace handkerchief might be scented, but what size,  $6\frac{1}{2} \times 4\frac{1}{4}$ , and a  $12 \times 10$  when he has a cold? Imagination reels before the vision of the future fully licensed awfully exclusive professional artist photographer; but should he be allowed to associate with the mere R.A.'s of the Academy?

Anyway, the fearfully common legend: "Sitters are requested to pay at time of sitting"—like hens do when they are on the deposit system—must on no account disgrace his studio walls; instead thereof: "Clients are commanded to walk backwards on retiring from The Presence of the High Art Operator at the Camera."

Never more than one portrait allowed per sitter, and the price? At least 25 per cent. on the victim's yearly income. Would that be exclusive and high toned enough? If these feeble suggestions serve in any way to pave the way, they are abso-blooming-lutely free from copyright!

A. FIELDSEND.

Silver Street, Lincoln. February 20, 1908.

#### SIMPLIFIED DEVELOPMENT OF AUTOCHROMES.

To the Editors.

Gentlemen,—Referring to the recent correspondence under this head there appears to be no reason for restriction to any particular developer. Theoretically, the developers of long factor give a finer deposit, and the following figures from the 1908 "Almanac" are interesting:—

Pyro (about) .....	5
Amidol .....	18
Metol .....	30
Rodinal .....	40
Dianol .....	60

The last being recommended by Messrs. Lumière for second development. Why pyro should be used for first development is not apparent, either from the results or from theory, nor is it clear why it is used. Possibly the "B.J." can enlighten us as to this.

Your correspondent on the matter recommends rodinal 1-10. Would it 1-20 give a finer deposit without reducing rapidity too much, but with more time for judgment of density?

It seems certain that two bottles only (developer and reversal solution) can produce equal results to those attained with the rather expensive collection first given.

It may not be generally known that daylight is not essential for development. Exposure to incandescent gaslight gives rapid blackening, thus making evening development practicable. If there any doubt as to the speed or sufficiency of the action a little magnesium puts the matter beyond question.

Discussion at this stage is very welcome, as helping to greater perfection and simplicity the precious power of colour in the form of which we are so much indebted to MM. Lumière.—Yours faithfully,  
T. H. JONES.

Fairfield, Mapperley Plains, Nottingham.

February 25, 1908.

Most of the points raised by our correspondent have been discussed on our pages or in the "Colour Photography" Supplement. French workers are now using amidol. Mr. Piper months ago advised using the alcohol, and MM. Lumière have approved its entire replacement by water. It has been customary, too, to expose to artificial light before re-development.—Eds. "B.J."]

SIR BENJAMIN STONE, M.P., will not seek re-election again for East Birmingham. He is seventy years of age, and though in good health at the present time he feels that he could not face such a contest would be necessary if the division is to be retained by the Tory party. It is with the view of giving his friends the opportunity of electing his successor well before the electors that Sir Benjamin Stone definitely informed the chairman of the executive, Mr. Norris, that he will not seek re-election. He has represented the division since 1895.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

#### PHOTOGRAPHS REGISTERED:—

W. Broughton & Sons, 102, High Street, King's Lynn. Photograph of Mr. and Mrs. J. H. Carleugh leaving St. Margaret's Church, King's Lynn.  
F. G. Wagborne, Trading as The London Photographic Company, 129, Newington Causeway, London, S.E. Photograph of Gunner Moir.

W. END.—We have handed your letter to the secretary of the P.P.A., who will doubtless reply to you direct.

TROPICS.—(1) Certainly, the prints are indistinguishable from those made by direct printing. (2) Yes, it is usual to employ the alum bath before fixing, washing in several changes of water before fixing. (3) Better apply to Wratten and Wainwright, who could advise you as to the time limit.

H. G. FISKE (Toledo, Ohio, U.S.A.).—Address Dr. J. H. Smith, at 9, Lessar Avenue, Clapham Common, S.W.

RED TONES.—I am an amateur, having some photographic prints which I am desirous of toning to a bright red colour. In your issue of January 31, you tell how to get this effect on certain prints with "Thiocarbonate." I do not understand this, so would be extremely gratified if you would explain in detail how I can produce a print of bright red colour either on plain silver or bromide paper.—CARLETON S. REYNOLDS (Brooklyn, N.Y., U.S.A.).

For P.O.P. prints a suitable thiocarbonate bath is that of Valenta:—Gold chloride 2½ grs., water 4oz; add to dissolve precipitate first formed, enough of thio-carbamide 10 grs., water 2 ozs. (about 150 minims will be required). Next add citric acid 48 grs., and water to 10 ozs., and finally salt 90 grs. For red tones on bromide paper about the best method is the copper toner (B.J. Almanac, 1908, p. 825), or the use of a good toning bath on a print which has been sulphide-toned. The bath is: Ammonium sulphocyanide 20 grs., gold chloride 2 grs., water 2 oz.

WAXING COMPOUNDS.—Would you kindly suggest a suitable formula for preparing a semi-solid waxing preparation for waxing bromides, which we understand is a mixture of white wax, spermaceti, and benzoline? (2) There is, also, we understand, a kind of varnish, apparently celluloid in acetone, which is also used for the same purpose, for which we should also like a formula, in order to compare this with the other method.—J. Y. AND SONS.

(1) A suitable formula is:—Purified beeswax, 50 parts; oil of lavender, 30 parts; benzole, 30 parts; gum elemi, 1 part. (2) We have no experience of a home-made produce. We should advise the so-called Zapon-lac, sold by the Leto Photo Materials Co., Ltd. "Lustralene" (Vanguard Co.) is also a good commercial form of the semi-solid waxing compound.

EXPRESS Co.—Try Berry and Roberts, St. Bride Street, London, E.C.

P.O.P. EMULSION.—Can you inform me as to the best emulsion for coating ordinary pulp board so as to get a similar result to P.O.P. I also wish to know whether it is advisable to float the emulsion on the board or coat with a brush?—SHAVIAN.

In the "Almanac" will be found, amongst the standard formulae, several for P.O.P. emulsion. Any one of these would be suitable, though the quantity of gelatine or water might require alteration to suit the specific case. In all probability floating will be found the best method of applying the emulsion, as this chills the emulsion quickly, and therefore prevents its penetration into the support. The trouble will lie not in making or applying the emulsion, but in the pulp board itself. P.O.P. emulsions contain free silver nitrate, which is at once reduced by metallic or other impurities, and the result will be black

spots. It might be possible to give the pulp board a preliminary coating of chrome, alum, and gelatine, *plus* a little citric acid.

**W. N. L.**—(1 and 2) It is often misleading to give directions in such cases, but we should say at least an ounce of mixture would be necessary to get detail in the stonework, etc., of the tunnel. We should say the light in the second case would be sufficient, but the plan of separately igniting three separate candles is bad for subjects such as groups. You require one or two lamps which can be fired simultaneously. This you could do, say, with the "Dega" lamp, of Chas. Zimmermann and Co., which is a very suitable apparatus for (3).

**VEHICLE, ETC.**—I would be greatly obliged if you could tell me of a substitute for gelatine in an ordinary silver bromide negative, such that it will conduct electricity well, or fairly well. Also, if any of the silver haloids are electrical conductors.—**J. C. WALSH.**

We regret that we cannot suggest any vehicle for the silver halides which would be a conductor of electricity. The silver halides themselves are conductors.

**A. P.**—The print is probably a bromide, toned by the hypo-alum method ("Almanac," page 825). We should say the new thio-molybdate toner would give similar results, and do so more quickly. See the article in our last issue.

**SCREENS AND OTHERS.**—In our next.

**PHOTOGRAPHING SHOP WINDOWS** (Reply to J. A. Coleman).—There is only one way of avoiding the defect—*viz.*, to prevent the opposite house being reflected. Altering the stand-point of the camera will not do unless it so happens that there is a dark and much taller house just to the right or left of those reflected, in which case a sideways direction of the camera might help you. The best means, however, is to get a tall dark van to halt in front of the shop window when the photograph is being taken. This will be reflected in place of the houses, and will not be noticeable. Another dodge, sometimes practised, is to photograph the window by flashlight at night. A good charge of powder would be necessary. One or two trial tests would show how much. The plate is not of great importance. Your present brand is all right.

**FINISHING ENLARGEMENTS.**—(1) Which are the correct pastels to use for tinting portrait bromide enlargements? I have tried Reeves' soft French pastels, both with and without powdered pumice, but the results are very poor, lacking in depth of colour. The article in the "B.J. Almanac," 1906, is the only one I remember having seen, and that does not give the correct pastels to use. (2) Is the method of applying the same as finishing in black and white—namely, stamps, cotton wool, etc.? I am unable to obtain Johnson's book on "Finishing," etc. Dealers say it is out of print. Is there any other publication on this subject?—**T. N. CHAPMAN.**

(1) If you re-read the article you refer to in the "Almanac" for 1906 you will see that the correct pastels to use are given. Also that three pages (848, 849, and 850) are devoted to details of the method of doing the work. If you read carefully again you will find all the information you require. (2) The publishers of Johnson's book are Marion and Co. Better write direct to them. We are not aware that the work is out of print.

**LENS APERTURE.**—The enclosed bromide print was obtained by putting a piece of bromide paper in lens cap, lens opened to full aperture, and camera racked out to infinity. In place of plate in dark-slide was a piece of thin black card with a large pinhole exactly in centre. Close to the pinhole was burned about 2 in. of magnesium ribbon. I understand the black circle represents the effective aperture. Can you please tell me the *f*/ value of that aperture? The lens is 5½ in focus. The makers say it is *f*/6.5.—**DOUBTFUL.**

If you state focal length correctly then the aperture is *f*/8.

**J. THOMAS.**—What you propose should be quite possible; but we should advise you to consult Messrs. Ross on the matter. A supplementary lens would be more likely to increase the speed rather than to slow the lens, but if not carefully adjusted it will disturb the corrections.

**H. S. (Reigate).**—We do not know the lens in question, but you cannot expect to get more than a few shillings for an old portrait lens unless it is by a maker of great repute.

**CONFIDENCE.**—The idea is very old, and has been published over and over again. All you can do is to register a trade-mark for such portraits, whereby to identify them with yourself. This will cost

you about £1. You should apply to the Registrar of Designs and Trade Marks, Southampton Buildings, E.C., for particulars.

**SENSITISING SILK.**—(1) Can you give me a formula for making photographs on material such as silk, etc.? (2) If by putting such a process on the market do I infringe any existing process? (3) Is there any such process on the market that is protected? (4) What would be the cost of such protection?—**FRANCIS O'ROURKE.**

(1) We do not know of a silver print-out method giving a sensitive material which will keep. You can try the platinum and Kallityp sensitizers given in the "Almanac," which are about the best formulae for the purpose. (2) In using these you would not infringe any patents, but you are not at liberty, of course, to use the word "platinotype." (3) The Platinotype Company prepare sensitized silks and other fabrics to order. (4) If you mean patenting, the cost of a provisional protection is £1.

**DAMAGED PAPIER-MACHE TRAYS.**—We have had in use for about twelve months several large papier-mache trays, which we use for washing prints, etc. These now are becoming rather pulpy at the sides and corners, and in time will be useless. I should be glad if you can tell me of a preparation I can use on them that will waterproof them, and also make them durable without any risk of injuring prints or negatives that may be washing in them.—**W. G. WOOD.**

If the papier-mache itself has become really pulpy we are afraid you will not be able to do much with them. The best treatment, however, will be to make them thoroughly dry and then give them two or three coats of good Brunswick black, taking care that each coating is quite dry and hard before a subsequent one is laid on. In place of Brunswick black, Aspinall's or similar enamel may be used. Either will not have any injurious effect on prints or negatives.

**VARIOUS.**—(2) What lens and speed of plate would you recommend to obtain fully exposed negatives of street views instantaneously? The lens required would be for 1-1, plate size. (3) Can you tell me the best means to reduce the halation on negatives caused by windows, etc.?—**A. E. H.**

(1) An electric or percussion-cap form of igniter is the best. We never heard of the use of oxhydrogen gas for the purpose. The outfit would be much too bulky. "Magnesium Light Photography," by F. J. Mortimer (Dawbarn and Ward, ls.). 2. A lens working at *f*/6 should be sufficiently rapid for average work with a plate of the highest speed, sold by any of the leading makers. A suitable focus for whole-plate is 10 or 11 inches. You had better consult the lens advertisements in the "Almanac." (3) Rub down with alcohol or the Basket globe polish reducer, recommended to "Edwin Hadley" last week, p. 152. We advise you to get the 1s. book of Dawbarn and Ward, "Finishing the Negative."

**A HUMORIST ON PHOTOGRAPHY.**—The humorist is Mr. S. R. Crockett, whose experiences with a camera in making mementoes of his travels were published some time ago by Messrs. Newman and Guardia, Ltd., and a delicious piece of writing it is, well deserving of a half-hour's reading, quite apart from its inclusion of the charming photographs which Mr. Crockett, all unskilled, was able to make with his "N. and G." The book bears the title "A Romancer's Local Colour," and Messrs. Newman and Guardia will send it post free for 7d. from 90 and 92, Shaftesbury Avenue.

**\* \* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

the exhibition of portraits by members of the P.P.A. closes to-  
row (Saturday) at 12.30. Some impressions of a provincial pro-  
positional at the exhibition appear on page 176. A protest by Mr.  
C. Turner against the remarks of Mr. Tilney, published some  
days ago, appears on page 182.

the essential portions of Mr. Frederick H. Evans' recent paper  
multiple mounting at the R.P.S. are reprinted on pp. 178 to 181.  
Mr. F. C. Tilney, at the North Middlesex last week, discoursed  
the art and practice of bromoil printing. (P. 175.)  
the suggested scheme of a National Photographic Portrait Gallery  
ld appear to be one in which the R.P.S. may take the initial  
steps. (P. 173.)

Mr. R. Luther has been appointed professor of photography at  
Eden. (P. 174.)

further details are announced as to the Brussels meeting of  
Photographic Convention. (P. 186.)

the death is announced of Mr. P. E. Newstead. (P. 183.)  
high-power telephoto lenses appear among patents of the week.  
(P. 183.)

the differences of tone in sulphide toning with pure and impure  
sulphide are the subject of an editorial. (P. 174.)

Mr. Wandersleb, in replying to a criticism of his paper on  
ortion, points out that the latter was a defence of the unsym-  
metrical lens. (P. 174.)

## "COLOUR PHOTOGRAPHY" SUPPLEMENT.

Dr. C. E. K. Mees describes a series of experiments on the  
anner in which "Uto" paper bleaches-out. (P. 17.)

British Screen-plate.—Announcement is made of the appear-  
ance on the market in a month's time of a British-invented and  
manufactured screen-plate to be known as the "Thames." (P. 24.)  
the Krays Screen-plate.—We give on page 23 some further  
details which raise a doubt as to the possibility of using a section-  
screen-plate film in cinematograph work.

Autochrome Plates.—Perhaps the most comprehensive examina-  
tion of the Autochrome plate is that of Mr. R. J. Wallace, pub-  
lished on pages 21 to 23.

two formulae for varnishes for the Autochrome plate have been  
recommended by Valenta. (P. 20.)

some points in the making of Autochromes are mentioned by Dr.  
Smith, of the well-known reproduction firm. (P. 20.)

Mr. C. Litchfield makes some suggestions as to an adjustable  
pur-filter for Autochrome plates by means of which variations in  
composition of atmospheric light may be compensated for. (P. 24.)

the recent paper by Mr. F. E. Ives gives particulars of the simpler  
method of measuring colours than the one described in our pages  
some months ago. (P. 19.)

## EX CATHEDRA.

### The Brussels Convention.

At the council meeting of the Conven-  
tion held last week Mr. F. A. Bridge  
was able to report very satisfactorily as  
to the final arrangements for the forthcoming convention.  
Among the papers to be read is one by Dr. W. Scheffer  
on the Autochrome plate; Mr. Martin Duncan is to lecture  
on screen-plate photography and show the latest applica-  
tions of the cinematograph to nature study; whilst an  
artist member of the Association Belge, M. Marisseau, is  
to deliver a lantern-lecture on Venice. With further con-  
cessions in the way of railway fares to London (for  
those who travel via the metropolis) and the  
announcement that members will have the opportunity of  
seeing the port of Antwerp from the river, there is still  
more reason for believing that the meeting will be larger  
than in previous years. That, too, is the indication of the  
inquiries and applications for membership addressed to  
the secretary.

\* \* \*

### The R.P.S. Portrait Gallery.

The scheme for the foundation of a  
National Photographic Portrait Gallery,  
that the Royal Photographic Society  
proposes to carry out, has received a crushing blow from  
a most unexpected quarter, for the R.P.S. is informed that  
a project of such value should be undertaken by some  
other body of greater importance and wider scope! It is  
not stated where a photographic body of greater impor-  
tance and wider scope is to be found, nor is it definitely  
suggested that a non-photographic body would do the work  
better; on the contrary, it is admitted that the R.P.S.  
should be allowed to have a say in the matter. The only  
ground for objection to present arrangements seems to be  
that the R.P.S. is not competent to decide who is worthy  
and who is not worthy to be represented by his portrait in  
the collection, but, so far as we know, the Society have  
not yet announced how this question is to be dealt with,  
hence the criticism can be at once dismissed as premature.  
No other grounds for complaint being yet stated we cannot  
weigh them in the balance, and by the time they are  
formulated we trust that the Society will have recovered  
from the shock of the first blow and be able to meet them  
with calmness and courage. If this scheme is not carried  
out by them we think there is very good reason to believe  
that it will not be carried out at all. The proposed gallery  
must inevitably be a thing of slow growth, and it will  
probably be years before the word "gallery" is properly  
applicable. In the beginning it must be a very small  
thing, probably too small for a specially appointed body  
of "more importance" to take much interest in. At pre-  
sent the R.P.S. does take an interest in it, and has avail-  
able all the organisation required for putting the scheme

on a workable basis, hence it is apparent that the Society forms the most suitable body for dealing with the project. Moreover, the membership of the R.P.S. being inclusive of all classes of men, little difficulty should be found in obtaining advice from any quarter whenever advice is felt to be required.

\* \* \*

#### The Professorship of Photography at Dresden.

We mentioned some time ago the intention of the Education Authorities in Germany to found a chair of photography in Germany at the Dresden Technical High School. This appointment has now been conferred on Dr. Robert Luther, of the Leipsic University. Dr. Luther is well known in Germany as an investigator in photo-chemistry, and the scientific press has borne evidence of his many researches on photo-chemical subjects. One of his earliest papers was that published jointly with Dr. Gros, in which were described the properties of certain dyes and leuco bases which have been used in the pinatype process. Dr. Luther is just forty years of age at the present time, and his appointment to the professorial chair will probably mean the continuous prosecution of research work under his direction.

#### THE USE OF SODA SULPHIDE.

MR. MUNKMAN's experiments in sulphide toning, described in his article of February 21, gave results that accorded with Mr. Blake Smith's experiences as recorded in our last issue. That is to say, both writers are agreed that, given pure sulphide and bleaching baths that have neither any additive nor solvent effect upon the image, the tones obtained are invariable. We think, however, that both lay rather too much stress upon the absolute necessity for using pure sulphide, and upon the evils of impure sulphide. The variety that we mentioned in our previous note, if treated in the way described, gives tones that are absolutely

different from those produced with pure sulphide, and many will differ as to the respective merits of the tones. With some subjects the less pure sulphide most undoubtedly gives by far the best tones, and to many people the pure sulphide tone is an objectionable one. The difference between the tones is nearly as great as that between the thiostannate and thiomolybdate tones described by Mr. Piper in his article on these two sepia tones, and moreover, the difference is one of the same kind. The ordinary sulphide gives a pure sepia-brown, while the other gives the photo-brown tint that is so popular among some workers and so much disliked by others. The soda sulphide that we are in the habit of using most frequently is labelled "pure," though its impurity is fairly manifest. The tone it gives is as different as possible from that produced by really pure sulphide, and boiling and filtering are both necessary in the preparation of the solution. A ten per cent. stock solution keeps well in a bottle with a greased stopper, and it gives us no trouble whatever. It is, of course, of a strong yellow colour, whereas the pure sulphide solution is colourless, or very nearly so, but our experience is that in a strong solution it keeps just as well, though in a weak solution the pure sulphide certainly keeps rather better. As regards constitution, no doubt the impure solution is a very complex mixture of sulphide and polysulphides. It may contain hypo, but if it does there is not enough to vitiate the results, and we can see no reason for abandoning a solution that gives an excellent and very desirable tone in favour of one that gives a tone of a quite different character. Of course, there are many degrees of impurity, and we should advise the purchaser of the ordinary sulphide from a reliable dealer. For the very purest sulphide it is necessary either to go to a manufacturer who prepares chemicals for analytical use or to make it oneself. The recrystallised pure sulphide is in quite white crystals like soda sulphite, while the ordinary sulphide is usually in green and yellow powdery lumps, and contains a considerable amount of insoluble material that has to be filtered out.

## DISTORTION IN SYMMETRICAL AND UNSYMMETRICAL PHOTOGRAPHIC OBJECTIVES.

HERR W. ZSCHOKKE, of the Scientific Staff of the C. P. Goerz Optical Works, Friedenau, near Berlin, has replied to my article recently published in this paper on "Distortion in Symmetrical and Unsymmetrical Photographic Objectives." I should, therefore, like to have this opportunity of briefly referring to the same.

An editorial note in the "British Journal" of February 21, page 134, confirms my statement in the previous article ("B.J.," January 31, 1907), as to the currency of the dogma regarding distortion, that amongst photographers it is almost generally accepted. It cannot, nevertheless, be denied that the dogma also holds sway in circles which are accustomed to consider these questions also from a theoretical standpoint. As one illustration of this fact, I may cite the following instance:—In the most recent prospectuses of the firm of C. P. Goerz the following sentence is to be found in the paragraphs devoted to the convertible objective "Pantar":—"Trotz dieser grossen Helligkeit—[1 : 6, 3]—gibt Pantar bei einer Gesichtsfeldausdehnung bis zu 85 deg. ein sehr scharfes, klares und bei symmetrischer Linsenkombination korrekt gezeichnetes Bild."<sup>1</sup> Here it is, however, implicitly stated that

the Pantar does *not* yield correct drawing in an *unsymmetrical* lens combination, i.e., if it consist of two Pantar lenses of different focal lengths. In reality, distortion in the "Pantar" is all the more completely corrected for its entire, expressly stated scope of application—*praeter propter*  $10 < N < \infty$ —the more the focal lengths of the single lenses ( $f_1 > f_2$ ) differ. This fact, which is applicable to all hemi-symmetrical convertible objectives, was stated by Dr. von Rohr in a special paragraph in his paper, already alluded to, published in 1897. In his book "Theorie und Geschichte des photographischen Objectives" (Berlin 1899), also referred to by Herr Zschokke, mention is again made with regard to this fact on page 55. In spite of this, it has evidently escaped the scientific advisers of the firm of C. P. Goerz.

Dr. von Rohr writes in the above-mentioned book, page 53:—"It is really the fulfilment of the tangent condition that is the more important thing, and one can rightly consider such symmetrical lenses as being *practically* free from distortion, through which the error of the older optical system finds its explanation." Herr Zschokke, in quoting this sentence, unfortunately overlooked the fact that the word "*practically*" is printed in italics, otherwise he would have found difficulty in quoting the sentence as a proof of Dr. Holm being right in stating that "symmetrical lenses are perfectly free from distortion."

<sup>1</sup> In spite of this great rapidity (1/8.3) the Pantar, with an extension of the field of view up to 85 deg., yields a very sharply defined image and correct drawing in a symmetrical lens combination.

Finally Herr Zschokke attacks my statement that practical defence can easily be obtained as to a very decided curvature of lenses (which are straight ones in the object) on the margin of the image field, if one of the well-known rapid symmetrical objectives be chosen for investigation and employed up to the image angle of 80 deg., or even 90 deg., which is often claimed them. As a refutation, he puts forward a photograph made by the Goerz "Dagor"  $f/6.8$ .

In reply I wish to state that the double anastigmat "Dagor"  $f/6.8$ , as shown by the curves published by me, is almost the best of the well-known symmetrical universal objectives as regards freedom from distortion; the symmetrical objectives of the greater rapidity, especially those constructed according to the Gauss type, show much larger errors.

Furthermore, it should be remarked that the photograph selected by Herr Zschokke does not contain a sufficiently exacting criterion for the "Dagor"  $f/6.8$ . A far better test would be as follows:—A white cord, to the lower end of which a weight is attached, is suspended free in air from the roof of a high building, the wall of which is not too white. This cord represents a straight line. A camera for 10 by 8 or 15 by 12 inches is placed at the window of a middle story of a house situated opposite. If a "Dagor"  $f/6.8$ , of focal length 120 mm. (4.7 in.) be fitted to this camera and sharply focussed on the opposite wall (in my investigation at a distance of  $A = 10$  yards),

the diameter of the image circle is  $D = 2f + \frac{2f^2}{a - f}$

in my case a little more than 24 cm. (9 7-16th in.) for an angle of 90 deg., up to which, the firm's prospectus states, the "Dagor"  $f/6.8$  goes when stopped down. The camera is now adjusted so that the image of the white cord appears at a distance

$\sqrt{\frac{D^2}{8}}$  in my case, therefore, 8½ cm. (3 5-16th in.), later-

from the middle of the plate. It then represents the side

of a square described in the image circle. Now, if the curve of distortion recently published by me for the "Dagor"  $f/6.8$  be followed to  $w = 45$  deg., it will be found that the side of the square, 17 cm. (6 11-16th in.) long, i.e., the image of the white cord, must show a curvature of 0.7 mm., if the lens corresponds exactly with the constructive data on which the curve is based.

It was impossible for me to entirely determine this calculated fact in the two examples of "Dagor"  $f/6.8$ ,  $f = 120$  mm., at my disposal, since the diameter of the circle of light in these, probably belonging to an older series of manufacture (No. 97,719 and No. 7,744), only amounted to 21 cm. (8¼ in.), that is, corresponding to an image angle of 83 deg. The curvature of the side of the square measured on the photograph corresponding to the last angle amounts in both examples to about ½ mm., and agrees sufficiently well with the error 0.4 mm. according to the calculation.

It is certainly not my wish to assert that these curvatures, although distinctly visible, prohibit the employment of a lens for the large angles indicated above, and I also consider that the far larger errors shown by some of the more rapid symmetrical lenses, even for smaller angles, of about 70 deg. angles more frequently occurring in practice, are generally not of a serious nature, i.e., the symmetrical lenses are *practically* free from distortion. If the above article be read carefully, it will be perceived that it is not an attack on the symmetrical lenses, but a defence of the unsymmetrical against remarks such as the quotation from E. Holm's book cited at the commencement of my lately published article. This defence was not based on mere vague statements, but on numerical data accessible to all who wish to prove its accuracy. The curves emphasise the fact that "there are unsymmetrical objectives in which, for the most important cases, distortion is eliminated to a very much more perfect degree than is possible in symmetrical objectives of a like rapidity."

DR. E. WANDERSLEB,

*Of the Scientific Staff of Carl Zeiss, Jena.*

## MR. F. C. TILNEY ON OIL PRINTING.

[On Wednesday of last week, the North Middlesex Society criticised the oil prints done by members, exhibited a number of examples of his own work in bromoil, and had some hints given on the practical details of the process. Omitting the details, we give the text of the lecture in the speaker's own words. We learn that the effects obtained by Mr. Tilney obtained general admiration, and we congratulate the North Middlesex Society on persuading him to step from the seclusion to which the critic is wont to withdraw himself. As one member expressed himself, the syllabus of the North Middlesex was thought to be deficient if it lacked a lecture by Mr. Tilney, and it is therefore good news to hear of his readiness to take his audience into his confidence in matters of photography.—Eos. "B.J."]

the orderly mind, which will have everything perfect, or on the attempt, before the moment of exposure, perhaps printing process excels platinum; but the fudger and the artist, who makes fine pictures from frightful negatives, wants a process that he can control. He is then not printing photographs at all; he is print-painting pictures by a bastard method—that is, neither art nor photography entirely, but a dash of both. Co-ordinately, he himself is required to be both painter and photographer. He can only tell whether he is of this choice blend by watching the effects his pictures upon others. Putting it broadly, and with a very general application, the worse photographer he is, the better will be his oil prints, and *vice versa*.

To use a controllable process certain things are indispensable. First, one must see that the print yielded by a certain negative is capable of improvement. Many photographers do not get far as this stage. Second, seeing it needs improvement, one must see also what would improve it. Fewer still arrive at this point. Third, one should know exactly how to set out the improvement, and how to pull all together to make a plastic completeness. This only an artist—either by birth or

education—can achieve. The artist by education is the best equipped.

Give him your oil print to develop, and he should, other things being equal, beat your photographer *per se* hollow. Now, what do I mean by "artist" and "education" in this connection? I do not mean the successful gold medallist of the life and antique schools, the winner of wall-paper competitions, and so forth. I place the ordinary photographer miles before these in the matter of landscape art. The educated artist is the man who has gone about wishing to use his eyes, and this is what photographers *do* do. He learns by heart all the gentle beauties that belong to the play of light over things, and he fosters his feeling for rhythmic line and mass by attempts at composition, which improve as the feeling waxes. In this manner does the photographer become qualified to use a method that is positively and completely artistic, and not in the least photographic.

But if a photographer use such a method *without* being able to avail himself of this adaptability, he would surely do better to use an automatic process that he cannot interfere with and spoil.

I do not say that there are not negatives from which a straight print in oil—if it could be done quite automatically—would not be beautiful and perhaps have qualities that a platinum print lacked. But the more beautiful the ideal photographic picture, the less is it likely to be well served by a method of control.

In the prints lent to me a few, and a few only, show the eager and grateful use of the control which oil-printing offers. If I had been allowed to see straight prints of the various negatives, I should have been able to tell how much these particular examples have *lost* at the hands of the oil printer. Here and there it appears as though no effort had been made to "treat" the subject at all; but there is nothing to be gained by simply dabbing to let come what may. Straight printing in oil is an anomaly.

As to the bromoil method I am positively untutored. But I do not think one is necessarily badly taught, if self-taught. One learns more effectually by bitter experience than by receiving precepts at one ear and letting them escape by the other, and by watching another man do the work. All one sees or hears has to be confirmed by practical experience before it becomes a personal possession. My very first attempt was better than the second, because I went carefully to work. In the second I went with too much bravado, and found I had dabbed on a quantity of pigment that I could not get rid of again. The pigment supplied I found of the consistency of new putty. It had to be "knocked up," as house painters say, with a considerable amount of medium. I had some of the motor petrol that is said to be indispensable, but I found it useless except for the ordinary purposes of similar volatile spirits. I tried linseed oil, but that took too much pluck out of the ink and was too slow a drier. Next I tried Winsor and Newton's copal oil medium, and found that answer very well, but finally found that a tiny touch of megilp worked better, because of its containing more varnish than the painting medium. I believe that in various contingencies all these may be profitably used. Sometimes, for instance, the megilp dries before one has said the last word to a particular passage, and to those who work slowly, as I do, this is a disadvantage, and the pigment is more conveniently kept workable longer by a touch of something less siccative in its action. Mr. Welborne Piper, the honoured inventor of bromoil printing, works, I understand, very quickly. But such prints of his as I have seen—only one or two, to be sure—do not show much attempt at treatment; they are rather particularly good examples of the straight print in the controlled process. But such work does not display the strength of the method. In

the four or five humble attempts—my very first, I beg you in mercy to remember—there will be seen to be some attempts to supply what pictorial qualities the originals seemed to lack.

In the matter of brushes, I use the *piéd de biche* so highly recommended by M. Puyo. They work very well; but I also have a set of the same sizes and make in the straight-cut pattern, and I feel bound to say that I find they work well too—just as well. Still, the difference is convenient for identification, for I make a rule of inking with the oblique brush and spreading with the straight. It has been said that "hopping," as it is called, is not only undesirable, but impossible, in bromoil printing. Against that I would plead to be allowed to "hop," all the same, if I am to use the process at all. The inexpensive wire arrangement of Messrs. Griffin is indispensable to me; it saves so much muscular effort, and can be used so lightly and so briskly that the hand cannot compare with it. "Hopping" does for me what a thinned-down pigment does for others: it gives smoothness of tone. But it also has this advantage: Since the ink is still what I call plucky, the utmost definition, contrast, and force is possible by using a brushing action instead of the tapping. This, for some reason or other, cleans out the lighter passages and sweeps the ink from them on to the darker, which rapidly gain strength of colour. In the landscape I show you the brushing action has brought out with much vigour the leaves in the light and shade of direct illumination. These trees were "brushed" after all the rest were "tapped," at which stage there was no difference of texture in them.

I find it possible, also, to take out quite white lights with a stiff little brush, dipped in water, and pure water I use liberally on the skies. Without this it is impossible to get the proper key of brightness. Upon the wet gelatine an inked finger seems to be the most useful implement for drawing clouds; but the other parts of the sky I can only graduate by "hopping."

In starting a subject one should take a print in hand and consider it for five minutes comfortably and quietly. Ask the question, "Now, what shall I do with this? What shall I make the subject, and what shall go? Having decided what is to be the *pièce de résistance* of the picture, next think out how it is to be worked up to, what must be suppressed, what broadened, what emphasised, what made more contrasty, and what taken out altogether. I have found it possible in this process to remove the upper portion of a large gable and to turn the bottom part into a tree, and such changes have been said to be impossible in bromoil.

F. C. TILNEY.

## A PROVINCIAL AND THE PROFESSIONAL PHOTOGRAPHERS' EXHIBITION.

AFTER the very varied standard of the last exhibition, the high standard of excellence attained by all the chosen pictures comes as a pleasant change. The visitor is immediately struck by the general lowness of tone of the prints, which still retain, however, a beautifully round bold appearance. Doubtless some of these prints have been intended for exhibition in out-door cases, when they would, perhaps, show to even better advantage than in a room. I do not mean to suggest that any of the exhibits are one whit too dark, for in fact the printing, whether in carbon, or in a few cases platinum, and in one albumen, is, like the negatives, an example of perfect technical work. The fact remains, however, that, even with a most fashionable clientele, there would be a danger of some of these beautiful specimens of correct tone-value being returned as too dark. "My face is so black, you know." If all of this work is exactly the same as sold to the customer, then the public taste is higher than I thought.

The method of selecting the exhibits and exhibitors has been very successful, but personal selection is never to be relied on. To speak of one firm whose specimens I know by heart, only one of their six ought to be included amongst their twenty best recent pictures.

Strong concentrated lighting is the almost invariable rule of the examples. Personally I have been going strong on this as distinctive of my own work; but apparently the general trend has been in this direction. Why this strong lighting should be called "Rembrandt" when used on profiles and three-quarter face heads and not otherwise, I fail to understand; but there are, shall we say for convenience, a few "Rembrandts." Very different they are, too, from the old examples. The high-lights, as with all the high-lights in the room, are not white paper. Here and there, perhaps, there is a spot the size of a pin-point, though a bright, sparkling high-light proves on examination to be full of gradation, and, in

places, nearly as low as half-tone. The shadows, to give the necessary breadth, are of course dark, but quite transparent. Overdevelopment, at least with these representative firms of the best in photography, has disappeared.

The backgrounds are all very dark, but there is no example, we think, of the perfectly plain ground, all grounds here shown being broken up very, very slightly. Downey has two fine oval whole-plate heads against a medium-tone ground, graded from top to bottom, the lightest part being against the head.

Two or three firms have examples of the multiple paper mounts, not more usually a ready-prepared commercial mount is used.

It is rather extraordinary that so many of the best firms should be using mounts with the printed borders. The copperplate certainly does not harmonise in any way with any process, and gives one the impression of bad taste. In spite of the price of platinotype paper, there are some cabinets masked out on to 12 x 10 papers and date-marked. Turner and Sarony have, in addition, added, presumably by a second printing, a border in middle tint round the portrait. Carbon is the favourite process; a colour between red-tink and sepia is a favourite.

The examples of multiple mounting are, as has been noted, few. Anyone who uses this method personally will not find the reason hard to seek. The time, trouble, and waste are very heavy, and in a high-class business it is usually found impossible to charge extra for the mount.

All the prints strike one as being perfectly finished. Those of C. Beresford have more of the amateur look than any, and are therefore duly commended by Mr. Tilney in his review from the artist's point of view. The very close cutting of the prints is mere eccentricity, and spoils the balance and composition entirely. In every case but that of a print of a girl preventing herself from falling the heads are far too big for the space they occupy. In one print it gives the sitter, a young boy, the appearance of a badly deformed and enlarged head. We really must digress to ask why Mr. Tilney should assume that the professional, through ignorance and incompetence, artistically falls short of the results desired by the public. This shifting of the blame from the broad shoulders of the public to the overburdened ones of the photographer is unjustifiable, and shows ignorance of the great and glorious British public. Kipling, though neither art critic nor photographer, but a keen observer of men, knows better. He says, in one of his short tales: "She knew that the public wants to be made to look pretty in a nice card at a moderate price." This is probably slightly misquoted, but woe to the photographer that doubts the truth of the meaning.

It is obvious that operators who can produce work of the style and beauty of that here shown could, at will, produce practically any effect desired, and the fact that the show has a certain general likeness merely proves that the business heads of the firms concerned are assured that this type of work is the one that sells. It shows lamentable ignorance of the public mind to suggest that even one in a thousand is prepared to take an absolutely truthful

likeness in preference to a very flattering and less literary photograph.

Only the other day I photographed an old gentleman in his ninetieth year who disliked medium retouched proofs because they made him look too old. Mr. Tilney forgets that the minority who know or care anything about art are infinitesimal, and the chance of a photographer having a sitting from even one in a year is smaller still. Is he to turn away all his other customers on the chance of getting that one? Supposing Mrs. A presents Mrs. B with a portrait that makes the donor look charming, vivacious, and young, is it human nature in any set for Mrs. B to return the compliment with a presumably artistic contraption that shows her in her worst mood at dusk?—for of course no photograph is a picture unless ugly.

To repeat, the general tone of the exhibition is repose, the lighting concentrated, the backgrounds subdued, the pose graceful, the process carbon, the mounts the manufactured article and light in tone. All of which latter look well, although exception might be taken to Mendelssohn's beautiful warm brown albumens on light grey mounts.

The speed of modern plates has created a new era in child portraiture. The charming expressions secured by Messrs. Turner and Drinkwater in their group of two boys and a dog is an example of an evidently instantaneous exposure, as is also their charming study of a child on a polished floor.

As we have said before, general low tone distinguishes the exhibition, but one or two lighter efforts relieve the show. A beautiful little coloured cabinet by Drummond, Young, and Watson is entirely in light tone; H. P. Robinson and Son have a nice study of a boy in a light suit against a light ground. Messrs. Ellis and Walery have two against light grounds, but are rather cut away from the ground—very suitable for stage portraits, such as theirs, but rather hard for ordinary work.

Moffat's fine Court-dress study is a great example of low-tone work. The high-lights are very small in area. Mr. Moffat has also a fine study of a man, where the hands are well placed and evidently characteristic. His piano group shows the difficulty of this class of work; though perfectly natural in pose and accessory, yet it smacks of the studio. The child studies are very charming. All H. P. Robinson and Son's children are perfectly childlike, whilst a fine child study by Miss Caswell Smith is, perhaps, one of the pictures that will be remembered longest.

Martin Jaconette has six very nicely lit portraits, which, even in this collection, are of noticeably excellent technique. I do not think the two back-view child studies by Lankester can be called professional portraiture. No mother would accept them. "I must see her eyes," she would say.

Gordon Chase also shines with a child group which is evidently what the public call a snapshot of three pleasant children examining the little dicky bird at last provided after long promises. "Look for the little birdie, darling," is as common now from mothers as ever it was from photographers. COUNTRY PRO.

THE LATE G. H. MARTYN.—We regret to record that Mr. George Henry Martyn, of the firm of Messrs. G. H. Martyn and Sons, photographers and photographic dealers of Cheltenham, passed away, after some few weeks' illness, in his 81st year. He had been in photography since the year 1851, and, we believe, in the early days contributed articles to the "British Journal." He had been resident in Cheltenham as a photographer for over thirty years, and was highly esteemed by his townspeople.

PHOTOGRAPHIC SURVEY AND RECORD OF SURREY.—The annual meeting will be held in the Electric Theatre of the Crystal Palace on March 14, at 4 p.m., when Mr. H. Keatley Moore (Mayor of Croydon) will preside, and Sir Benjamin Stone, M.P., will deliver an address. A lantern lecture on the work of the survey will be given at 8 p.m. A selection of 700 prints will be exhibited in the South Nave, and will remain on view till March 21, during which period a lantern lecture will be given each evening in the Electric Theatre. Full particulars of the work of the association may be obtained from the hon. sec., Mr. Frank F. Wood, 11, Milton Road, Wallington.

"ENSIGN" ROLL FILM MONTHLY COMPETITION.—The three-guinea Holborn-Ilex magazine camera offered every month by Messrs. Houghtons Ltd. for the best negative on Ensign roll film, has again gone to India, a sign that Ensign films are in very great demand there. The prize-winner is Mr. R. J. Macnabb, The Residency, Bolarum, Deccan, India.

CATFORD AND FOREST HILL PHOTOGRAPHIC SOCIETY.—The third annual exhibition will be held on March 27 and 28 next at St. John's Hall, Devonshire Road, Forest Hill. Entry forms may be obtained from the hon. secretary, Mr. W. T. Browne, 169, Woolstone Road, Forest Hill.

PHOTOGRAPHS OF SHOP WINDOWS.—Apropos of our reply to a correspondent, we have received from Mr. S. Porter, of Landsend, Chippenham, two photographs of the window display of a tobacconist in his town, to whom a prize was recently awarded. Mr. Porter does not mention the method which he employed to get rid of reflections of opposite buildings, but the photographs show that he has been extremely successful in dealing with the subject.

## THE MULTIPLE MOUNTING OF PHOTOGRAPHS.

[Mr. Frederick H. Evans' lecture and demonstration before the Royal Photographic Society was reported in our columns at the time, but on the publication of the full text in the current "Photographic Journal" we must do our readers the justice of quoting from it such portions as can be separated from the context of the examples to which the lecturer made constant reference. Even thus shorn of its adornments, the paper conveys the best instruction in the modern practice of multiple mounting which is at present available, and amateur workers in particular may be referred to it. The personal labour attached to the work will, we fear, discourage its use by the professional, or will limit it to the fortunate few who can command their own prices—and some customers.—Eds., "B.J."]

Even the simple sticking of a print on to a plain piece of paper or card may easily give rise to error. The position of a print on its mount is not a matter allowing for any incursion of personal "taste"; there is but one proper place for it; and that, as a first practical instance, I would like to insist is *not* in the centre. It has always been the practice of the professional mounter to put it there, I know: mainly, I suppose, because that is the easiest and quickest; the centre of a mount is so quickly and easily struck and the picture placed there as quickly. Most illustrated books have their pictures

Fig. 1.

Fig. 2.

mounted so; and the inevitable and ugly result is that the picture looks as though it had dropped, or that the paper had been trimmed unequally and that the picture was really *out* of centre. Compare figs. 1 and 2.

### Rules for the Margins of the Mount.

The top margin must be less than the side margins; both side margins must be equal; and the bottom margin must be greater than the side margins. Actual proportions will vary with shape of print and size of mount, but the above forms a general rule from which there is no appeal; for though the following exceptions seem to upset this "no appeal" dictum, the result of the exception is but to give the appearance the above rule enforces.

An exception to the rule comes in when we have a long narrow (vertical) print to deal with; if we adhere to the usual proportions, those good for a squarer picture, we shall feel that the top margin looks as though it had been accidentally cut off. If the same picture is mounted with a much greater proportion of top margin and the sides reduced, it will appear precisely as though the usual rule had been followed; the length and narrowness give this illusion. We are compelled, if our æsthetic sense worries us in these minutiae, to give such proportions; a sense of proper balance is not obtained otherwise. The same exception obtains in the so-called "landscape shape" picture. This must be treated in an analogous way to the vertical print; the sides must now be much greater than they would be for a squarer print, and the bottom margin slightly less than the sides. This latter may be varied. In some cases where extreme width of print is not sought to be enforced, a greater proportion of bottom margin to that of the sides may be allowed.

### On Acquiring Certainty in the Choice of a Multiple Mount.

It may sound very arbitrary to say that there is but one right way, and that there is no appeal from it; that there is but one way of placing a print on a mount as to proportions in margins which will fully satisfy the critically æsthetic sense; but I am sure that if those who dissent from me here will work habitually in this search after the one and only way, they will come to recognise that there is really

no appeal from the one proper way, when it is found, of apportioning the margins; that it is right one way (the way I have indicated) and wrong every other. "Taste," that doubtful quality we unduly pride ourselves upon, is no helper or arbiter here; its only use is to help us to know when we are wrong, not to tempt us to insist that our wrong is right, right because our "taste" has invented it. The eye gets gradually trained to an instinctive sense of correct proportions. It is not a thing to be learned in a moment, but has to be patiently worked for by study of good examples. The best method of gaining it is to get into the habit of analysing our impressions. When we feel satisfied, work out why we do so; see if we can account for there being no cause for, or sense of, discontent. If we are in the least unsatisfied or restless, analyse that, and see what gives rise to it, and when mounting try and try again, by no matter what minute or numerous alterations, till we reach that curious but delightful state when we can exclaim, "Ah! that's it. I've got it now. I feel that's right at last!"

Having thus settled the proper placing of the print on its mount, we may now proceed to consider its treatment if it is to be placed on more than one piece of paper; and few I think will nowadays be content with the mere sticking of a print on a single mount, however correct that may be in colour.

In the first place, I should like to insist that simplicity be made the chief aim; and though you may smile as you study some of my examples, extending as they do to as many as eight papers, if the result is a simple one, if it has an effect of simplicity, my axiom has been observed. Mere number, mere complexity of tints and papers, only add to the difficulties, both technical and artistic, and distract attention from the picture. It should not content us if the comment, when we produce our latest gem, is, "Oh, what a pretty mount! what a number of papers!" That comment, as to the wonder or beauty of the mount, should come last, not first.

As we are dealing specifically with multiple mounting, I need not argue as to whether it is not best to be content with but two papers, that is, only one between the print and the final or bottom mount. That is very often a quite sufficient method; but as we are now dealing with another method, which is really an easier way of arriving at the French method of surrounding a drawing by ruling ink lines and filling up some of the spaces between them with faint washes of colour—I will deal only with multiple mounting, which is a reaching after the French method by superimposed layers of tinted papers cut to various widths.

A point we may notice here is, what sort of framing we desire to use. If we want a wide or elaborate frame, our mount must be studiously simple; if we are content with a narrow and simple moulding, or a *pas-partout*, we may be elaborate in our mount; but we must not be elaborate in both mount and frame, else we shall reduce our picture to the lowest value of all, instead of its having the greatest.

### Choosing Mounting Paper No. 1.

Our first step is to decide on the colour and texture of the final, the bottom sheet; this must be of a tint that will best show off the main effect of the picture. And here our first difficulty arises, in the fact that our print will most likely not have all its sides of the same depth of colour. If it is a portrait study, we may have the sitter's light dress at the bottom and a dark background at the top; if it is a landscape, we shall perhaps have a heavy foreground at the bottom and a light sky at the top; and the colour of mount that will suit one may injure the other. We must therefore choose a tint that will sufficiently enrich our dark portion, but not ruin the values of the lighter portion of the picture. If our mount is to consist of only two pieces, it will be easiest to do this by the first layer being so chosen as to just detach the print from the main mount, and help the values of both it and the print. In the case of so simple a

mount as two layers only, the first one may be anything from one-eighth to half an inch. But if we are to use three or more pieces, then the first layer is best kept to one-eighth or less; it will otherwise usurp too much attention.

Supposing that our subject is a portrait against a rich dark background, I would suggest first trying a light bottom mount, though at first this may seem wrong, for a dark subject or background seems naturally to call for a dark mount to relieve it. But you will find that very often a dark mount will rob your background of its depth and richness; and that a suitably light mount will enrich it and give it new value. And here comes in the advantage of using three or more layers; there is a certain shock to the eye in a dark background coming directly on to a light mount, it looks too cut out, or cut off; but if this is bridged over by suitably toned intermediate papers, the shock is not felt. A case may occur where a light background must be kept as light as possible, and then a dark mount is best.

It may, of course, happen that a print having a dark background will look as effective on a dark mount as on a light one; if, that is, the subject is so rich in itself as to make the background to it comparatively negligible.

### The "Design" of a Multiple Mount.

The width of the various pieces of paper used are, of course, determinable solely by the worker's taste and skill in design. The only method of gaining success is the old one of trial and error; plus infinite patience; plus the refusal of everything that is not absolutely satisfying to one's most critical judgment; and plus an ample supply of papers to work with. As the total effect of this sort of mounting is to form an inner frame to our picture, I like to follow the French method I spoke of; and if our ruled lines are made by very narrow dark (or light) colours, and our washes made by faint tints between them, we shall achieve a similar effect, only in a much easier way.

### Avoid Colour in the Mount.

Before considering the methods of choosing and using the various tints and widths of papers, I would like to say a word as to colour. No colour should be selected or used that will have a final effect of colour as colour. If we do, we shall inevitably spoil or vulgarise our print and only achieve a garish, inartistic effect. Ours is a monochrome art, and we must beware how we endeavour to enrich it by means of colour in our mounts. The tints of our papers must be such that they are felt only as low-toned washes, or narrow dividing lines; their colour must not be felt in and for itself, but only as a differentiating something to what is on each side of it.

Many of the tints in my collection of samples are not procurable now; it is one of the exasperations of this work that fashion rules here as elsewhere, and what is in stock one "season," is not to be had for love or money the next. Also it must be acknowledged that it is often next to impossible for a maker to so re-colour his vat that an identical tint shall be repeated. Therefore, if one falls violently in love with a certain tint, it will be well to lay in a reasonable stock of it; as, perhaps, later on, when it can no longer be had, a series of mounts cannot be completed. Against this must be placed the caution that what one likes very much at first may soon pall or prove too difficult to use, and a large stock of it will prove a nuisance. But papers that are at one time tired of, or found difficult to use effectively, may afterwards, with the advent of other tints, prove quite valuable. Also a tint that is found quite impossible when used in any width of one-eighth or over, may, when used as a mere dividing line between other tints, prove extremely useful. It is also as well to try and find out if a tint that we propose using in marked widths is really permanent in colour. I lately had some frames back from exhibition and was amazed at my lack of taste in using a certain colour, so bad it now seemed to me; but on lifting it up I found the reason—all the tint I had chosen for it had faded out of it, leaving the horrid effect that so amazed me. Of course, if a print is destined for the portfolio only, this need hardly concern us, as the short time it is exposed to strong light will not hurt it. But the prints I referred to were on the Irish Exhibition walls for six months, and in I know not what strength of daily sun.

### The Practical Way in Multiple Mounting.

To turn from the theoretical to the practical. I find it a good method to save time when selecting tints, to go through one's stock and cut a small piece, say 7 x 5, from each paper; I then true up

each corner, and sort them in lights and darks, etc. These form a sort of palette of tints and can be very readily chosen from as we proceed. Suppose we have decided that our mount shall be made up of these cold blues: I choose what I think will be best as a first layer, and put the top left-hand corner of the print into position on it, showing the exact margin to be used. Holding them together in the left hand, I pick up the next chosen tint and place it behind the first two. Holding them out at arm's length I try the effect of various widths; when satisfied I place the next tint behind them and again test the whole; if satisfied I place them on the final sheet, and as near as possible the proper position on it with the left hand grasping the whole. Holding all up at arm's length and in an even light, the entire effect (as regards the top of the print, at any rate) can be judged. If the slightest feeling of discontent is felt, I make alterations in widths, or change a tint, in either a space or a line, spending anything from five minutes to half an hour until quite satisfied.

I find the time spent—I won't say wasted, for the mere critical exercise is valuable—in this fascinating work is not in the actual cutting and pasting, but in the selection of tints and widths. Sometimes nothing will go right; the colour of a print proves baffling to anything like perfect treatment; when this is so I lay that print aside and give it a rest; later on it will likely come right quite easily when one feels fresher. When at last satisfied with my experimental mount, I lay the collection carefully down where it cannot be disturbed; indeed, sometimes I measure and note the various widths and papers; for it is aggravating if they should get dislocated and one has to do all the experimenting over again. It is now easy to pick out from stock a sheet of each of the papers to be used; and though I urge the advisability of being liberal in the size of the pieces to be cut from, a wise economy will lead us to look among our cut pieces rather than always to cut from a whole sheet. To save time in turning over scraps for this purpose I keep them in piles on a shelf, each pile being of associated tints—greys, creams, blues, browns, etc.

### Securing Squareness of the Tints.

Before sticking our print on its first paper, it is imperative to see that it is truly squared up. The least error will be so magnified with each successive piece of paper as to lead to an almost unbelievable result. Each layer may be measured and cut with scrupulous accuracy, but any initial error in the print itself being out of square will throw all out and lead to a quite absurd amount of error at the end. Placing the print on its first sheet I attach it by a small dab of paste at the top right-hand corner only, and only at this one corner for this reason: it is best to use as thin papers as possible to keep our mounts reasonable in bulk, but thin papers, especially if of a soft and absorbent kind, cockle so easily as to make this multiple mounting very difficult to keep neat and workmanlike-looking. If we attach by this one corner only at first, and paste the other, the top left-hand corner, when all the papers are in position, it will materially lessen the risk of cockling, as each paper can be put perfectly straight with an equal pressure over all, and the risk of uneven tension being set up is more easily avoided. It is also as well to use the mountant as dry as may be. With some papers that will cockle, do what one will, it is as well to put the paste under the body of the print, not behind the corners of mount; the uneven tension may then be a little less visible. But this plan does not make so neat a finish, as the corners will not lie flat on each other, but stick up a little, and so rob the final effect of its full sense of design, especially if many fine lines have been used. Pasting by these two top corners only is usually sufficient, especially with papers that lie quite flat. Any of the modern mountants, of which the euphonious "Higgins" was the forerunner, will give a sufficient adhesive power without being too permanently attached. I think it is also well to lay stress on a certain inherent value in our photographic picture, and not to rob it of its identity by pasting it down all over. No original drawing of any worth is ever so treated; it is always interesting, sometimes valuable as evidence, to turn up the back of an engraving, drawing, or etching and see what style and texture of paper had been used. Our photographic picture is also a thing of itself, and should be so respected, and not have its identity lost by being made one with some other and alien piece of paper or card. Besides, some future owner of your, perhaps unique, print may not approve of your

scheme of mounting, and will want to detach it and treat it afresh; and one should only have to soak off a print as a quite last resort.

#### De-mounting Prints.

How often, indeed, have I had to renew mounts myself! Something one was quite content with at first proves by lapse of time to have been an equally marked lapse of judgment or taste, or a further selection of papers has made a better treatment in parts of it possible. Or, if we are blessed with a good "critic on the hearth," and She receives with a cold sniff of disapproval the new mount we hold out in conscious pride, it is good, when with fresher eyes and unbiassed vision we are ourselves able to realise its shortcomings, to be able to detach it so easily and safely. But even though stuck in this slight manner, it is best not to attempt to remove it from the front. I find a safer way is to place the print face downwards, lay hold of the corner of the paper next it and pull it back; as soon as it begins to leave the print, hold the latter firmly down by the thumb of the left hand on the minute portion thus showing, and continue pulling the mount away from it. To pull a mount off a print in this manner is quite a different thing to pulling a print off a mount; it may then either tear or may split, and leave the print there so thin as to injure the tone value of that corner when re-mounted.

#### Marking Mounting Papers for Trimming.

We have so far only attached our print to its first paper; we have now to trim that to its required margin. This I prefer to do by the guillotine cutter. A knife, on zinc or glass, leaves an undesirable edge or burr to the paper, very often quite spoiling the effect of the mount when seen in oblique lighting. The burr may be taken off by rubbing down with an ivory paper knife, or the thumbnail, but on some papers that leaves a shiny surface that ruins the appearance of the mount.

Unless we are gifted with a very accurate eye, it is best to mark the width to be cut away. I use a hard retouching pencil, and with it make a small dent on each side, top and bottom, when I want to cut. Placing this on the guillotine cutting board, I make these dents come accurately at the cutting edge by denting the paper with the thumb just behind the pencil mark, so that it will be just cut off. This will ensure perfect straightness, and by placing a steel straight-edge over the paper close to the cutting edge the paper will not buckle as the blade comes down along it, however thin the paper may be, or even if not quite dry, though that latter is a very unadvisable thing to risk.

As regards cleanly cut edges, etc., all workers have their predilections; mine is for neatness, precision, and high finish, when I can attain to them. But this is not, I think, inconsistent with artistic breadth; it should not merely connote finicking or niggling work, undue sense of detail, etc. Breadth of impression need not infer slovenliness of technique. One sometimes sees the affectation of a roughly torn edge to either—or both—the print and the mounting paper. This is done, I suppose, to imitate the deckle-edge naturally given by hand-made paper. But such an edge deceives nobody; and, why imitate? why not be content with the natural condition of the paper we are using? These methods never add to the beauty of the picture to me, but rather detract from it. Picture, mount, and frame should make a harmonious whole, with no disturbing elements in it.

In considering our widths of margins we must bear in mind when deciding on the bottom one that if we want to place a title or impress a monogram we must leave room for it. The widths round top and sides are governed by rule, but that at the bottom may vary, sometimes having a good effect fairly close up, and sometimes only right when much further away. As a rule, this bottom width should be twice or more that of the sides.

#### Some Rules in the Use of Tinted Surrounds.

As to design in this work; for a series of papers merely placed one upon the other without suggesting some sort of design, becomes only wearisome and meaningless. Here, of course, the personal equation is everything; nothing but experience, and the most fastidious rejecting of everything that does not quite fully convince and charm us, will tend to success. There are so many ways, alas! of going wrong in this little department of our photographic hobby.

When narrow spaces are ruled in, enclosed by very fine lines, the various spaces must never be exactly repeated, as this gives a dull

sense of monotony; it is mere meaningless repetition with no effect at design; but if the spaces are nicely contrasted, variety of effect will be gained, and a sense of design given. A close approximation to a faint wash of colour may be gained by making a very slight change of tint, one grey, for example, being followed by a very slightly darker or lighter one; or by using the same tint again, but enclosing it by very narrow lines, dark or light, by which the colour between them is heightened or lowered, as may be desired.

Black, it must be remembered, is only possible when used in lines of extreme fineness; and, though so narrow, they are easy enough to cut, but they must be cut correctly at the first, for if not found fine enough they are all but impossible to re-cut, and a new sheet must be used. If a real change of paper is made for such an inlay, to get a different tone, care must be taken not to over-do it. If kept in due restraint quite elaborate effects may be gained by quite simple means. Using light papers of marked texture will also give a good inner-frame effect.

#### The Effects of Light and Dark Tones in a Mount.

It will now be seen that the choice of successive tints for either lines or spaces must be very carefully made so that they do not in any way alter a tone value or effect. A too light tone will very perceptibly darken another light one; while a too dark tone may unduly lighten the one we have already chosen as the only possible one at that stage. Colours that one would not think could go together may, when used in such moderation as very narrow lines or very narrow spaces, prove quite acceptable: therefore do not too readily give up a strong colour, not till it has been tried in very narrow lines, etc. Brown, blue, and grey sounds rather alarming as a suggestion for a mounting scheme; but in a case where I wanted to increase the effect of sombre richness by harmony rather than by contrast, a little scheme of two shades of blue with narrow brown lines enclosing a dark grey, came quite successfully; and though it has five papers, the result is quite simple, with no feeling of undue elaboration.

When choosing grey papers, avoid the cold steely sort, they are too difficult to use, except, and that rarely, with special shades of blues; with any other tints they seem to get too pinkish, or too blue, and are quite impossible. It is the neutral range of tints we shall find most useful. In browns, avoid the hot or yellowish sorts; they work up too suggestive of mere colour.

One good comes from the non-ability of getting the same paper in succeeding seasons, and that is that one is compelled to design and work out new effects; grooves or mannerisms get difficult, and variety is enforced, which is a very wholesome testing of one's individuality. I may perhaps suggest a plan of my own: never to use an already completed mount as a pattern, unless one is making an exact replica for a special purpose, and with a perfectly similar print, similar in depth of tone, that is; for the same subject, if lighter printed, will need a quite different treatment in its mount. I prefer to think out each scheme afresh, repeating from memory rather than from example; this compels variety and the finding of new ideas, it avoids monotony, and largely increases one's experience.

Sometimes a darkish line is needed round a print, not close to, or next it, but just enough away to give the feeling of being close up. It actually next the print it would not have the frame effect desired; it is got by cutting the first layer to, say, one-eighth or three-sixteenths and then using a fine dark line, and then repeating the first paper to whatever width may be desired for the next space. If we repeat the idea as the outer border it will be best to make the line much broader, say one-eighth instead of the fine line we first used. This will vary the effect while having the value of repetition, and make a simple design but of very good form. Also, if this outer dark line came directly on to the light basal mount, it would be a little abrupt in effect, and it is much improved by the softening down the outer pale grey line gives.

#### How to Store Multiple-Mounted Prints Flat—the Cut-out Mount.

One great objection to this multiple system of mounting is that when prints accumulate and a pile is made, they cannot lie flat; they are all so much thicker in the middle than at the sides that the pile is a very unsightly and unhandy one, either in a drawer, cupboard, or portfolio. One way out of the difficulty is to keep the mount as simple as possible, using the fewest number of papers that one can, and then to use the last layer but one, untrimmed. If

then treat the very last sheet as a cut-out mount, cutting the opening in it so as to show exactly the desired proportion of the last one, which we left untrimmed for this purpose, and then lay the whole down on cardboard, the cut-out, especially if we can get it in a quite thick paper or thin board, will largely allow for the thickness of the papers inside it, and a pile of such mounts will be found to lie quite flat. I find it best, when using this method, to paste the untrimmed sheet on to the cardboard foundation, lay the cut-out sheet on to it, and then adjust the print and its mounting papers in position in the opening, all having been very scrupulously measured and squared up first. The true-ing up is more essential in every step in this method than in any other, as the cut-out sheet when finally put into position reveals errors in a most cruel fashion.

FREDK. H. EVANS.

#### THE KODAK COMPANY'S PROFESSIONAL DEPARTMENT.

It is probably no secret, even to those not engaged in the business of photography, that for years past the powers of the Kodak head office in Clerkenwell Road have looked after the professional photographer as persistently as so large a buyer of goods deserves. Photographers throughout the country have been kept promptly acquainted with the Kodak wares by the firm's travellers, and by the exhibitions of apparatus and apparatus which have been periodically held in the large centres. The local demonstrations, notably those of the Aristodion paper, have been very efficiently organised, and have been a means of bringing the professional worker directly into touch with the maker. These measures, however, were formerly taken almost exclusively in regard to the Kodak plates and papers, several details of which may be said to have been produced specially with a view to their employment by the portrait maker. During the last year or two professional supplies of all kinds have been taken up by the Kodak Company and worked chiefly from the London

of which are here kept ready for examination in a moment. We saw here some examples of a new design of background, to be called the "New Gallery," which are fine specimens of delicate painting, and lend themselves excellently to vignettes and effective portraits and light tones. Cameras and other photographic equipment equally figure in the department, as do also various types of furniture and accessories, in the design of which the makers are making a commendable departure from the hoary conventions of the studio. Of some other

quite new apparatus we may be able to speak later. It is sufficient to mention now the blocking and embossing room which is attached to the department in order to permit of urgent orders for mounts being promptly dealt with. Another shop devoted to apparatus enables such work to be quickly done, whilst a tour round the stock-rooms was sufficient to convince us of the powers conferred on the Clerkenwell staff by their large holdings of floating stock. Altogether it is satisfactory to find the professional photographer so

in Clerkenwell Road and from the provincial houses of the West-End and City depots still remain exclusively amateur. The firm's energies in the new direction have been in the hands of A. J. S. Catford, under whom is a staff drawn from the ranks of the profession, and therefore familiar with their customers' special requirements. A recent visit to Clerkenwell Road showed us the measures taken for dealing with this branch of the business. At hand to the exhibition gallery, decorated in a simple yet expensive style, which a photographer would profit by studying, a spacious floor, provided for the display of all the apparatus and accessories necessary in the professional photographer's establishment. The two photographs, taken from opposite ends of the premises, will give some idea of the variety and size of the stock thus available for inspection. As shown in the centre of the larger room, at one end of the show-room a studio is arranged with means for testing the systems of lighting (the Aristo lamp, arc lights, etc.) sold by the firm. A well-fitted dark-room immediately in the rear stands at the disposal of the photographer who wishes to test his exposures here himself. On the right in the smaller photograph can be seen a double block of backgrounds, some two dozen

thoroughly catered for, even to the provision of a certain amount of reading matter, issued monthly as "The Professional Photographer." This publication contains in each issue reproductions of notable photographers' work, and the professional worker can be advised not to omit a glance through its pages.

**OPTICAL AMALGAMATION.**—The current number of "The Prism," the little magazine issued by the Bausch and Lomb Optical Company, of Rochester, New York, announces a business alliance between the Bausch and Lomb firm, the Carl Zeiss Optical Works, Jena, and Mr. G. N. Saegmuller. The Zeiss Works become part owners of the Bausch and Lomb Optical Company, although the latter will still preserve its separate existence, and will see no change in its management. The two firms will co-operate to assist each other in every possible way by mutual confidence as to methods of manufacture, results of research, and business organisation. Mr. Saegmuller contributes to the alliance his mechanical skill and qualifications as an inventor of optical appliances and a constructive mechanic.

## MR F. C. TILNEY AND THE EXHIBITION OF THE P.P.A.

[The following letter, addressed to the secretary of the Professional Photographers' Association by Mr. T. C. Turner, of Hull, apart from its controversial passages, is particularly deserving of a careful reading, in that it represents the experience of a most successful and alert photographer. We give practically the full text of the letter. Mr. Tilney is well able to take care of himself, and we, on our part, need only say that Mr. Tilney was asked to give his impressions of the photographs, chiefly *because* he could not be suspected of looking at them from the photographer's standpoint, and secondly, because he was a stranger to the exhibitors.—Eds. "B.J."]

MR. T. C. TURNER writes:—My curiosity is aroused by the unsympathetic criticism in the "B.J.," which in the main suggests that the show is pretty dismal with its "banal smoothness," its "unalloyed vulgarity," its evidences of "old-time principles, methods, and traditions," and the absence of "freshness, which is now undoubtedly lacking in almost all professional work."

It is a scathing indictment, and it would be interesting to know if Mr. F. C. Tilney is a gentleman fitted by professional experience to be our judge. His comments strongly remind me of the lectures my late father received from his pupils (myself included) many years ago. My father was a photographer, then making some thousands a year, achieving a success based largely upon a keen knowledge of human nature, and—I am inclined to believe—a good deal of "tinkering" (if that is its proper description) "with the drawing and modelling of the features."

I find this evening that since those days I have photographed some seventy odd thousand sitters, and—alas, for well-sounding theory!—am more than ever convinced that "the old-time principles and traditions" are in the main quite safe to follow if success in business is the aim in view. The postulate of the professionals of the seventies and eighties were that clever lighting would make the sitter look his best, that clever retouching would eliminate the worst facial effects of business anxiety or physical or temperamental weakness, and that clever posing might make even the slipshod, slovenly youth look, for a few moments, a man.

And now we are assured in the columns of our leading professional journal that the modern amateur goes to work "with a captivating freshness of attack uncontrolled by studio paraphernalia," unenslaved by "studio routine"! Can anyone be seriously convinced that the old ideals of a good operator can be reached without long-continued practice, without personal contact, in a studio with hundreds, or even thousands, of sitters of every type.

Reading this somewhat ungracious criticism one is reminded of the habit which prevails with some writers on photographic subjects to represent professional photographers as men deficient in artistic abilities, and, persisting in this attitude, they ignore the fact that millions of their fellow-men and women have been, and are to-day, frequenting these studios and accepting with pleasure the work they, as critics, affect to despise.

There are scores of British photographers (and some have contributed to this small exhibition) who from end to end of the kingdom will probably be remembered when our unfriendly critics, who pose only in print, have long been forgotten. Is this popularity all based upon humbug?

Mr. Tilney mentions the reception of an amateur portrait with the remark from his sitter, "Well, that's the first photograph of myself that I have ever had taken that did not look smug, and it's the only one I ever liked." To those of us who spend our whole lives on the studio floor from early morn to dewy eve "the boot seems on the other leg," if our sitters describe to us their experiences at the hands of amateur friends honestly. It is pretty safe to assume that the public have always, and will always, recognise the fact that under the well-arranged studio light they are more likely to secure what is sometimes described as "a flattering likeness." And sooner or later the most enthusiastic itinerant photographer of the umbrella-brown-paper school comes to be of the same opinion.

The eternal law of "the survival of the fittest" applies as much to photographers as anyone else, and the people who paint portraits or take photographs regardless of the tastes or desires of their sitters are likely to weary pretty quickly, and men who embark thousands of pounds in photographic establishments are not long in deciding what the public require and will pay for. If a thousandth part of the unfriendly nonsense written about professional photo-

graphy carried conviction with it there would be a debacle such would sweep away the whole lot of present-day photographer "studio paraphernalia," "porcelain faces," and all.

No doubt there is a lot to be said for unretouched work, and a critic has omitted to recognise the fact that now many hundreds of "professional" photographers are working on these happy and economical lines; but there is also an unfortunate side to the medal, and it is that the public refuse to give more than 6d. or 1s. a dozen for the copies, and even when enlarged to 12 x 10, toned sepia and beautifully fuzzy, the market value seems to rise no higher than 1s., or mounted on an artistic shade of brown paper, 1s. 2d.!

But, reverting to the P.P.A. Exhibition, it is possible the "lay" public, after the assurance that "at least they will have the advantage of a select and bird's-eye view—a better view than can be obtained by promiscuous glances into the same old series of 'stagnant cases'"—will not feel over eager to swarm into the "B.J." Gallery, but we must hope all the same that it may be the means to establish a bond between (professionals) which shall be "commercially advantageous."—Yours sincerely,  
T. C. TURNER.

## Exhibitions.

## ILFORD PHOTOGRAPHIC SOCIETY.

THE annual exhibition of this society was held on February 26 and 27 in the Town Hall, Ilford. There was an interesting invitation section, and in the open competitive class the judges, Messrs. H. Bennett and E. T. Holding, made the following awards:—Silver plaque: (No. 92), "Profile Portrait," Oscar Hardee; bronze plaque: (88), "Roses," C. H. Hewitt; bronze plaque: (103), "Long Reach," H. C. Hornsey; bronze plaque: (162), "In the Transept—Wells," F. C. Boyes; bronze plaque: (166), "Diligence," F. A. Tinker.

## Patent News.

*Process patents—applications and specifications—are treated "Photo Mechanical Notes."*

Process patents—applications and specifications—are treated "Photo-Mechanical Notes."

The following applications for patents were received between February 17 and 22:

ANHYDROUS THIOSULPHATE.—No. 23,217 C/07. Improvements in the manufacture of pulverulent anhydrous thiosulphate. Verein Chemischer Fabriken. George William Johnson, Lincoln's Inn Fields, London.

FOLDING CAMERAS.—No. 3,630. Improvements in folding cameras. Arthur Lewis Adams, 24, Charing Cross Road, London.

ARC LIGHT.—No. 3,700. Improvements in electric arc illuminating apparatus, more particularly for use in photography. Josef Schmidt, 31, Bedford Street, Strand, London.

PHOTO-TELEGRAPHY.—No. 3,701. Improvements in the method of transmitting graphic signs, photographs, and the like by means of electric current. "Polyphos" Electricitäts-Ges. m. b. H., Bedford Street, Strand, W.C.

DEVELOPMENT-TANKS.—No. 3,721. Improvements in development tanks for photographic plates. George Frederic Green, Riccarton Studio, London Road, St. Alban's, Herts.

PHOTO-TELEGRAPHY.—No. 3,728. Improvements in apparatus for the telegraphic transmission of designs, portraits, and the like. Guillermo T. Guillén Garcia, 23, City Road, Finsbury Square, London.

DRY MOUNTING.—No. 3,737. Metal folder for use in connection with dry mounting of photographic prints and the like. George Wilson Morgan, 393, Union Street, Aberdeen, Scotland.

PORTABLE DARK-ROOMS.—No. 3,790. Improvements in portable photographic developing chambers. Jakob Wojciechowski, 31, Bedford Street, Strand, London.

CINEMATOPHGRAPHS.—Improvements in cinematograph camera. Ernest Francis Moy and Percy Henry Bastie, Greenland Place, Camden Town, London.

CAMERAS.—No. 3,849. Improvements in photographic camera

Thomas Charles Naylor and Otto Sichel, 1, Great James Street, Bedford Row, London.

IMPROVED PLATE FOR CINEMATOGRAPHIC PROJECTIONS AND APPARATUS FOR THE MANUFACTURE OF THE SAME. Jean Leon Muller and Jules Rousset, 7, Southampton Buildings, London.

IMPROVED PLATE FOR CINEMATOGRAPHIC PROJECTIONS AND APPARATUS FOR THE MANUFACTURE OF THE SAME. Jean Leon Muller and Jules Rousset, 7, Southampton Buildings, London.

# COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

IMPROVED TELEPHOTO LENSES.—No. 18,121, 1907. The invention consists essentially of a set of negative lenses which can be used singly or in groups, the combination of two or more enabling the camera extension to be greatly shortened for a given magnification. This combination can be satisfactorily made only with lenses of selected foci and radii, such as are described below by way of example.

Fig. 1 shows in section the rear portion of a lens mount, such

Fig. 1.

is used with telephotographic lenses, provided with a form of improved negative lens system. Fig. 2 is a diagram to show necessary optical data.

The adapter A, which carries the lens system, is provided with a flanged end a, against which the end lens B<sup>2</sup> abuts and in front of this lens are placed the remaining negative lenses B<sup>1</sup> and B<sup>3</sup> being used in the illustration. The lenses employed are chromatic doublets or triplets, the former only being shown in the arrangement illustrated. At the back of the lens system is used a retaining split ring C which holds the lenses in position,

Fig. 2.

lens cells b however themselves fitting closely in the adapter. The set of lenses is introduced from the inner end of the adapter, which is removed from the main lens tube D for the purpose of inserting or removing the lenses. At the other end of the tube is the ordinary positive photographic lenses. In the illustration the lenses are shown of three different foci, the strongest being in the middle, and by properly arranging the order, inserting the diaphragms if necessary, various corrections can be made, while great variation in size of the image can be obtained using fewer or more independent lenses.

By this system the same telephoto lens can give a great range of magnifications with a small extension of the camera.

The following are the essential data for the arrangement of lenses illustrated, the letters of reference being shown on the diagrammatic view, Fig. 2;

$d$ ,  $d^1$ ,  $d^2$  are diameters;  $t$ ,  $t^1$ , etc., thicknesses, and  $r$ ,  $r^1$ , etc., radii of curvature for the surfaces.

## FOR LENS B:

Focal length = 65mm.

Positive element of flint glass, refractive index = 1.62521.

Negative element of crown glass, refractive index = 1.523.

$d$  = 25mm.

$t$  = 1mm.

$t^1$  = 5.5mm.

$r$  and  $r^1$  = 28mm.

$r^2$  =  $\infty$ .

## FOR LENS B<sup>1</sup>:

Focal length = 30mm.

Positive element of flint glass, refractive index = 1.61873.

Negative element of crown glass, refractive index = 1.53751.

$d^1$  = 19mm.

$t^2$  = 2mm.

$t^3$  = 3.2mm.

$r^3$  and  $r^4$  = 14.3mm.

$r^5$  = 172mm.

## FOR LENS B<sup>2</sup>:

Focal length = 50mm.

Positive element of flint glass, refractive index = 1.7509.

Negative element of crown glass, refractive index = 1.5005.

$d^2$  = 26mm.

$t^4$  = 5mm.

$t^5$  = 2.35mm.

$r^6$  = 26.20

$r^7$  = 18.93mm.

$r^8$  = 95.26mm.

The lenses are not separated, but are placed as nearly as possible in contact with each other. Alfred Edward Staley, 19, Thavies Inn, London, W.C., and Owen Wheeler, Strathmore, Prince's Road, Weybridge.

ROLLER-BLIND SHUTTER.—No. 4,830, 1907. The invention consists of a roller-blind shutter, by means of which exposures can be made during the movement of the curtain in both directions. It consists in enabling both movements of the curtain to be produced by means of a torsional spring arranged in or in connection with either or each of the curtain rollers and adapted to be tensioned in both directions, so that for the movement of the curtain in both directions, the drive can be imparted without the use of reversing mechanism. The absence of reversing mechanism such as has been used in shutter-mechanism of the same type wherein the actuating spring can only be tensioned in one direction, is an obvious advantage, and as compared with the mechanism wherein a straight wire spring or plate spring is adapted to be bent in opposite directions for moving the curtain upwards and downwards respectively, the torsional spring has the advantage of greater compactness and convenience. Reginald Hadden, for the Optische Anstalt C. P. Goerz Aktiengesellschaft, 44/46, Rhein-strasse, Berlin-Friedenau.

DEATH OF MR. P. E. NEWSTEAD.—Mr. Percy Eland Newstead, more popularly known as "Peter Eland," died on Saturday last at Idle, Bradford, at the age of thirty-eight. Although little known to photographers of to-day, those of ten and fifteen years ago greatly appreciated his contributions to the photographic press, under his pen name, and his humorous "pen" sketches, for Mr. Newstead was an accomplished black and white artist, with an immense amount of humour. He was with his friend, "Richard Penlake," one of the original sub-editors of the now defunct "Practical Photographer" in its early days at Bradford. Photography not affording scope enough for his vein of humour and his rare and versatile gifts, he entered the theatrical world, and during the past few years produced a large number of pantomimes, dramas, and music-hall sketches. His lectures on photography always drew crowded audiences, for his subjects were always unique, and he could see fun in everything. The terrible physical handicap under which he ran the race of life from boyhood to the grave failed to cripple his restless humour, and he was ever the incarnation of a jest.

## Dew Apparatus, &c.

The N. and G., H.S. (high-speed) Hand-Camera. Made by Newman and Guardia, 90 and 92, Shaftesbury Avenue, London, W.

Not to know the hand-cameras of Newman and Guardia is, of course, to write oneself down as ignorant of the perfection to which the construction of this type of camera is susceptible, and we can claim to be familiar with the various patterns of N. and G. cameras, and with more than one, through regular use. Yet we must confess that, until the fact was recently brought to our notice, we were unaware that Messrs. Newman and Guardia manufactured a camera which is a variation of the well-known "Special B," in that it possesses, in addition to the shutter of the latter instrument, a focal-plane shutter, which allows of the separate use of both exposing devices, and, in fact, is adjustable to keep one open while the other is being used. Such a camera is, of course, one with the widest range of possibilities as regards speed, for the front shutter gives exposures down to one-half of a second, and the focal-plane allows of times from one-tenth to one 800th in the convenient manner familiar to those who have used it on one or other of the "N. and G." patterns of reflex camera.

In addition to this range of shutter movement, the "high-speed" camera is made so that the modern lenses of largest aperture can be mounted upon it. Thus it will accommodate the Zeiss Planar ( $f/3.8$ ) or the new  $f/4.5$  Tessar instruments which are naturally of the greatest value in securing full exposure at the higher speeds and in circumstances of dull light when ordinary snapshot photography is out of the question. It is not merely in the provision of these

facilities that the camera earns our commendation, but equally in the way in which every movement is arranged for convenient manipulation. If this were not so and if the workmanship of the camera were below the "N. and G." standard, the camera would be scarcely preferable to instruments which can be purchased for a twentieth of the price. It is the perfection of working, finish, and the fact that the working quality will be found unimpaired if the camera lie by for a year or more that give the "N. and G." its value and justify its price. In saying this we are but repeating the experience of users, but it is necessary to recapitulate such facts before reciting the movements which the camera possesses, otherwise the reader might well question the wisdom of paying a price which would purchase a suite of furniture or a motor bicycle.

As we have said, the High-Speed is a modification of the "Special B," and externally in the quarter-plate size is an inconspicuous black box measuring 6 x 6 x 10 inches, and with just one projection, the key of the focal-plane shutter. As in the "Long-Focus" pattern of reflex, the focal-plane shutter is removable and replaceable in an instant. It is, of course, the one-tension pattern with alteration of the speed by width of slit after exposure. The front shutter is the well-known N. and G. pattern, all the parts "get-at-able," the setting done from the top of the camera and the speed alterations made very conveniently below the shutter. The two-way rise of front, the provision of tested finders, levels, and focussing scales are all on the lines of the "Special B," the rear portion of the camera carrying focussing screen, and dark slides, changing box, film pack or roll-holder. As we have said, it is enough to compare the "High-Speed" with other N. and G. models to award it the highest praise. For the full particulars of the camera, application should be made to the firm at 90-92, Shaftesbury Avenue, London, W.

The Soho Head-Screen and Soho Eye-Rest. Sold by Marion & Co., Soho Square, London, W.

Messrs. Marion, in designing a new form of studio head-screen have produced one adjustable in every direction by means of a ball socket clamp. The fittings of the screen are in nickel, and the

base and support is japanned, giving the whole apparatus a handsome appearance in the studio. The price is 21s.

An "eye-rest," serving to assist the operator in securing a portrait with the eyes of the sitter in just the right direction, has also been placed on the market by Messrs. Marion at 7s. 6d. It stands 6ft. 6in. in height, and the movable block on which the sitter's head is to rest is pushed at once up or down, and remains where it is placed.

THE "FULMENAR" ANASTIGMAT.—Questions put to us from some readers of the review last week of Messrs. Sichel's  $f/6.8$  anastigmat show that a portion of our review has been misunderstood. Speaking of the lens as "not of the very highest rapidity" intended, of course, to distinguish it from the  $f/3.5$  and  $f/4.5$  anastigmats issued at treble the price of the "Fulmenar." Our tests of the latter showed that its working rapidity is actually claimed for it, a fact which, apparently, was not understood in our paragraph.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—On Thursday, March 19, 1908, Mr. W. R. Stretton will lecture upon "Tones and Values." Visitors will be heartily welcome at the meeting, Ye Olde Napier Tavern, 25, High Holborn, at 7.45.

## CATALOGUES AND TRADE NOTICES.

"THE AGFA HANDBOOK."—The 1908 edition of the handbook of formulae and instructions for the use of the Agfa plates and chemicals comes from Messrs. Chas. Zimmermann and Co., St. Mary-at-Hill, London, E.C. It contains revised directions for use of the Agfa plates and a good deal of practical information on working methods which involve, as so many do, the use of one or other of the world-famous Agfa developers. This includes hints on the use of formal for the time development of ordinary and Autochrome negatives, notes on the use of the Agfa intensifier, rapid fixer, and wash powder. There is also a directory of dealers known to stock Agfa products. The new "Handbook," obtainable free, is certainly a volume to have at hand.

"CITY SALE" BARGAIN LIST.—A catalogue of many pieces of second-hand apparatus, hand cameras, stand cameras, studio cameras, enlargers, and lenses has just been issued by the City Sale and Exchange, 81, Aldersgate Street, London, E.C. The list includes a great many of leading makers' goods, which are offered in good, perfect working, condition at greatly reduced prices. A postcard to the City Sale will bring the list, which certainly ought to be studied by those purchasing apparatus for the season.

## Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

## FRIDAY, MARCH 6.

Ingham Camera Club. Lantern Lecture. W. L. F. Wastell.  
 Camera Club. "Photographic Chemicals."  
 Photian Photographic Association. "Imitation and Imagination." T. N. Hepburn.  
 London Photographic Society. "Press Photography." A. Hirschfeld.  
 Photographic Society. "Around London." F. C. Williams. "Gower."  
 R. C. Harris.  
 London Photographic Association. Rotary Carbohydrate Paper.

## MONDAY, MARCH 9.

Borough and District Photographic Society. *Photographic News* Prize Slides.  
 Photographic Society. "Autochrome, Demonstrated." Frank Cooper.  
 Borough and District Photographic Society. "Portraiture." J. T. Tanner.  
 Photographic Society. "Enlarged Negatives on Negative Paper." E. H. Jackson.  
 Photographic Society. "A Scamper through Holland." W. Sumner.  
 Hampton Camera Club. "Servia and its People." C. R. Howdill, A.R.I.B.A.

 Worth Photographic Society. "The Camera." J. W. Baker.  
 Windsor Photographic Society. Rotary Carbohydrate Paper.  
 London and Provincial Photographic Association. "Personal Notes on Tones and Values." W. R. Stretton.

## ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, March 3, Mr. E. J. Wall in the chair. Mr. Martin Duncan gave a lecture on "The Autochrome Plate Applied to Natural Science," and prefaced his remarks with a reference to

the Gravier method of developing Autochromes. This he found not to give the increased transparency claimed by its advocate, nor was the colour-rendering as correct as that when the Lumière directions were followed. Mr. Duncan developed an Autochrome exposure, a photo-micrograph of the screen-plate itself, and projected it upon the screen. He then exhibited a number of slides of photo-micrographs and nature subjects, illustrating particularly animal mimicry. In the course of a discussion a number of questions were asked, in replying to which Mr. Duncan gave some hints as follows: In taking his photo-micrographs he uses acetylene light and a Lumière filter. He intensified all his slides: the omission of this part of the process he found sacrificed brilliancy. In the case of a slide that was somewhat too dense, he found a very weak Farmer's reducer brightened up the Autochrome. During the last few months he had noticed no frilling of the plates. His own opinion as regards varnishing was that it was essential; he doubted the recommendation of Von Hübl to substitute for varnishing the immersion of the Autochrome in a solution of glycerine, leaving (on the slide drying as much as it would) a small proportion of the glycerine in the film. He had not tried rodinal as a developer. The meeting concluded with a hearty vote of thanks to the lecturer.

## Commercial &amp; Legal Intelligence.

"BROWNIE" AND "ENSIGN" FILMS.—In the Chancery Division on February 25, before Mr. Justice Eve, Kodak Ltd., brought an action against Mr. W. G. Grenville, dealer in photographic accessories, of Corporation Street, Birmingham, for an injunction to restrain him from infringing plaintiffs' trade-marks and from passing off other goods as and for plaintiffs' goods.

Mr. Walter, K.C., explained that in 1906 Mr. Blake, a representative of his clients, sent an hotel porter to the defendant's place of business with a written order: "Please give bearer one 'Brownie' film, 7d.," but the porter was given an "Ensign" film. Mr. Blake then went to the shop himself, but no explanation was offered him, and in due course a writ was issued against Mr. Grenville. Upon receipt of this defendant wrote asking that the writ should be withdrawn, and saying that he was ready to give every reasonable assurance that their rights in the matter should be respected. The plaintiffs subsequently applied for an interim injunction, but no order was made. The issue of fact to be tried in this case was whether the assistant told the porter what the article was that was being supplied.

Mr. Blake gave evidence as to sending the porter to purchase the film. Cross-examined by Mr. Ogden Lawrence, K.C., for the defendant, he denied that he gave the assistant no chance of explaining what he had done.

Mr. Berry, the defendant's assistant, said that when the porter came to defendant's shop they had no "Brownie" films, and so he offered the "Ensign" film and asked the porter whether it would do. The porter looked at it and then took it away. He denied that he had any instructions to push the "Ensign" films.

Mr. Grenville, the defendant, gave evidence that he had no intention of deceiving, and had given no instructions as to selling "Ensigns" instead of "Kodaks."

Mr. Lawrence submitted that it would be monstrous to grant an injunction against the defendant, for such a proceeding would be out of all proportion to any injury that could possibly have resulted to the plaintiffs.

Mr. Walter said his clients had heard there were firms passing off "Ensigns" in Birmingham, and Mr. Blake sent to three firms for "Brownies," and two of the three gave "Ensigns."

His Lordship, in giving judgment, said he had no hesitation in accepting Mr. Grenville's statement that he gave no instructions which would lead to the selling of the "Ensign" films in preference to "Kodak" films, and he believed him when he said that, so far as he was concerned, it was a matter of entire indifference whether a "Kodak" or "Ensign" film was sold. He therefore acquitted him of any intention to pass off "Ensign" goods for goods of the Kodak firm. At the same time he thought that in this case Mr. Grenville had been the victim of an over-zealous shopman. He was sure that he would be employing a Nasmyth hammer to crack a nut if he were to grant an injunction in that case. He believed he was dealing with a perfectly honest tradesman, and he would be visiting on him

a penalty which was not deserved if he were to grant an injunction; but he knew there were other consequences beside injunctions, and he had to say how the costs in the action were to be borne. He believed that Mr. Grenville would have done better if he had admitted at first that a mistake had been made; but he had not done that, and the case had come up for trial. He came to the conclusion on all the circumstances that this was not a case in which he could give the plaintiffs costs, but at the same time he did not think he could order them to pay costs. He would therefore make no order in the action as to costs or otherwise.

#### NEW COMPANIES.

**HIGH STREET PHOTOGRAPHIC COMPANY.**—120A, High Street, Margate. Partnership for five years from February 1, 1908. General partner: C. H. Walker, above address. Limited partner: J. Pitcher, Hazlewood. Palmers Green, Middlesex, contributing £50 cash.

## News and Notes.

**CONVENTION NOTES.**—The *Ministre des Chemins de Fer* has kindly placed a large steamer at the disposal of the local committee for a cruise on the Scheldt on the occasion of the Convention visiting Antwerp (July 10). Members will therefore have an excellent opportunity of viewing the wonderful panorama of shipping for which this port is famous, and obtaining snap-shots galore of good river subjects.

The papers and lectures already arranged for include "The Structure of the Autochrome Plate," by Dr. W. Scheffer; "Belgium" (illustrated by about 100 slides by members of the Association Belge), Mr. M. Vanderkindere; "A Chat on Venice," by M. Marisseau, the artist; and a specially prepared lecture-demonstration, by Mr. F. Martin Duncan, entitled "Screen-Plate Photography and the Latest Application of Cinematography to Science."

Arrangements have been made with most of the railway companies whereby members residing more than thirty miles from the metropolis, who hold Continental tickets to and from Brussels, may obtain tickets to and from London, at a single fare and a quarter.

**A PHOTOGRAPHER'S GRAVE.**—Letters received at Cape Town from Portuguese West Africa mention a touching instance of the devotion of natives in tending the grave of a white man buried within their borders. Two years ago a party of prospectors, representing a Cape syndicate, "trekked" from the Transvaal to Portuguese West Africa. One of the number, a Mr. Leslie Barclay, of Cape Town, who was the photographer of the expedition, died, and was buried in a lonely desert grave on the banks of the Luiana River. The survivors left on the grave Mr. Barclay's camera. It was useless through constant wettings, warped, and twisted, but it made an appropriate "headstone." It now appears that the few natives in the locality regard the camera as an important part of the white man's burial rites, and although it has been repeatedly carried away by hyenas, they are zealous in recovering the battered and dilapidated instrument, and restoring it to its original position at the head of the grave.

**THE OXO COMPANY** is offering to enlarge photographs of their patrons. Anyone who sends a guinea's worth of coupons with a portrait will receive, free of charge, a well-executed enlargement, on pearl grey mounts, entirely free from advertising matter.

**CITY SALE AND EXCHANGE.**—On Saturday evening, February 29, the employees of the City Sale and Exchange, Aldersgate Street, Fleet Street, Lime Street, and Sloane Square, held their annual dinner at the Manchester Hotel, Aldersgate Street, E.C. Mr. Richard Green in the chair. After the Royal toast with musical honours had been given, Mr. Green's health was enthusiastically drunk in champagne, to the strains of "For he's a jolly good fellow." Songs were rendered by several members of the company, with Miss Dorothy Green at the piano. At the conclusion of the dinner the whole company proceeded in taximeter cabs to the Lyceum Theatre, where seats had been reserved in the stalls for them, and concluded a most pleasant and enjoyable evening.

**THE NEW SOCIETY OF PAINTERS AND SCULPTORS.**—It is a sign of the times that painters are now so often combining into small bodies

in order to make a direct appeal to the public. The few established societies are almost all "close," and do not admit the work of outsiders. The dealers are practically as inexorable. The young painter has no chance but to wait till he is no longer young, by which time he may have made a reputation in a series of lucky strokes few and far between. The "New Society" is composed of ten painters and a sculptor. Most of them are about 25 years old, but it must in fairness be said that in the case of two or three their style is quite mature. E. Whitney-Smith shows accomplished statuary; M. Norsworthy some impressions of white sunlight; Louis A. Sargent displays much power and promise in woodland scenes, interesting examples of under-exposure effect in paint; E. H. Fischer exhibits studies of wild beasts, full of action, but not gymnastic; J. H. Amschewitz revels in ideal and poetic subjects, something in the manner of Shannon, fine in colour and decoratively impressionistic in form; Carruthers Gould's work is already well known. We expect both his name and his accomplished work will be of advantage to the society. G. W. Philpot must get more attractive subject matter. Amazing simplicity and dexterity of methods are shown in J. Nickal's water-colours. J. H. Lobley's work culminates in a fine portrait, and lastly are the very distinguished sketches of A. S. Wilkinson. The exhibition is at the Rowley Gallery, 140, Church Street, Kensington. We wish it well, but fear it is not for the man in the street, and, until he is educated, picture painting will remain uphill work. Photography is his only hope; that may perchance turn his mind into pictorial channels.

**THE "FALLOWFIELD" SMOKER.**—The annual smoking concert of the staff of Jonathan Fallowfield, the well-known firm of the Charing Cross Road, was held on Friday last at Frascati's Restaurant, under the presidency of Mr. F. W. Hindley. A large company of the staff and their friends of both sexes filled the hall and bestowed full approbation upon an excellent programme of songs, recitals, and other "varieties" of entertainment. Among those present were Mr. Winter and Mr. Hill, of the Imperial Dry-plate Company, Mr. S. H. Fry, Mr. Edgar Scammell, Mr. Wain, of "Focus," Mr. Pharoah, of "Photography," Mr. P. R. Salmon, of "The Photographic Dealer," Mr. A. Lawrence, of Wellington and Ward, and Mr. A. W. Brooks and Mr. G. E. Brown, of "The British Journal of Photography." In response to a vote of thanks to the chairman, Mr. Hindley expressed the pleasure it gave him to be present. On his vacating the chair to catch his last train, his place was taken by Mr. A. J. Goode. A most successful evening came to a conclusion shortly after 11 o'clock.

**"THE SCOTTISH FIELD,"** a monthly illustrated paper devoted to sport and outdoor life, has commenced the publication of a series of "Photographic Notes," and in its March issue deals fully with the Scottish Salon and the celebrations attending its opening. The issue contains a number of excellent sporting pictures from negatives obtained with Thornton-Pickard apparatus.

**THE BLENNHEIM CLUB.**—On Thursday, March 12, Mr. E. J. Wall will give a lecture on "The Spectroscope and its Applications," at the rooms of the club, 12, St. James's Square, S.W., at 8.30 p.m.

**UNITED STEREOSCOPIC SOCIETY.**—A gathering of the London members of this society took place on the 23rd ult. at the residence of the president (Dr. S. Walshe Owen). A programme of the summer excursions and meetings was arranged. During the evening Mrs. Owen kindly presented the awards of the annual competition, the plaques being the gift of the vice-president, M. Victor Selb, of Brussels. The result of the competition proved as follows:—Best collection: Silver plaque, S. W. Shore; Class A—Landscape: Bronze plaque, A. J. Snow; Class B—Still life: Bronze plaque, P. Snow; Class C—Architecture: Bronze plaque: A. T. Mole; Class D—Open: Bronze plaque, A. Lester; while the following received hon. mention: Messrs. F. Low, S. W. Shore, J. Veitch, A. Lester, and G. W. Stannard. Although at the moment the society has its full complement of forty members, the hon. secretary, Mr. A. J. Snow, of 74, Lloyd Road, Walthamstow, will be glad to send particulars to prospective members. The membership is confined to stereoscopic workers.

MR. HAROLD HOOD writes us that his private address is now "The Fields," Nunthorpe, S.O., Yorks. Those who have reason to write him, apart from the business of Hood and Co., Ltd., are asked to make a note of the change.

## Correspondence.

We do not undertake responsibility for the opinions expressed by our correspondents.

Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

### SULPHIDE TONING.

To the Editors.

Gentlemen,—In a postscript to a letter in your issue of February 28 Blake Smith makes a statement to the effect that in sulphide of sodium sulphide yields silver sulphide. By silver sulphide some the compound  $\text{Ag}_2\text{S}$  is implied. But from some experience I made in 1906 (published both in the "Journal" and "Lancet" of that year) I came to the conclusion, on what seemed an irrefutable experimental evidence, that an alkaline solution of sodium sulphide in the presence of gelatine reacts with silver to form a dark-brown body held in pseudo solution—a body cannot by any permissible licence of nomenclature be called silver sulphide. From this solution no solid is separable by immediate filtration through the most retentive filter-paper, but on course of time the solution slowly deposits very small quantities of a dark-brown solid. To the investigation of this precipitate, does not at all resemble ordinary silver sulphide, I hope to devote some of my summer-time leisure.

I may add that the advisability of reducing the bromide content of ferricyanide-bromide bleacher to the proportions suggested in experiments in the paper referred to has in the meantime come out to the test, and has been fully justified by results.—Yours truly,  
DOUGLAS CARNEGIE.

Castle-on-Tyne.

Coming to pressure on our space this week several letters, paragraphs, and notices of new apparatus are held over.

## Answers to Correspondents.

Matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., Wellington Street, Strand, London, W.C. For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 7d. each photograph, to cover cost of registration fee, form, etc. Unmounted copies of each photograph must be sent with the

### PHOTOGRAPHS REGISTERED:—

Mr. E. C. Brown, 34, Castle Street, Llangollen. Photograph of John Poultons, Esq. Brown, 10, Bolton Street, Bury, Lancs. Two Photographs of Combined Photographs and Drawings of: (1.) Prel Cotton Mill by Night; and (2.) Pilot Mill by Night, both at Bury, Lancs.

NOTE.—(1) What is the strength of the commercial solution of sodium bisulphite in the amidol formula for development of bromes on p. 10 of "Colour Photography" Supplement February 7, 1908? Is it the same solution as mentioned in solution of the MM. Lumière instructions (sol. bisul. lye)? Is any unevenness of the film of the gelatine strip filter behind lens (it coddles slightly in the mounting) in any way the definition and precision of the image and the correction of the lens?—A. D. GOSTIEFF.

We believe it is the same. MM. Lumière refer to the bisulphite solution which they place upon the market, and no doubt when using the same preparation. (2) If placed behind lens it will certainly affect the definition; whereas, if placed in front of the lens, a little unevenness will be of no account. PROFESSIONAL PHOTOGRAPHY.—(1) Is there a book published which gives the up-to-date modes of work in developing, printing, etc.—in fact, the full working particulars of a professional photographer? (2) Where can it be purchased? (3) Price?—CLONMEL.

Only book we can advise you to get is "Professional Photo-

graphy," by C. H. Hewitt. Iliffe and Sons, Vol. I. and II., 1s. each.

E. A. P.—You should send us something more than an untuned P.O.P. print if you want an opinion of the portrait. We should not consider it up to the standard of the leading exhibitions. One defect is the symmetry of the lighting; the light tones on either side of the face need differentiating in brilliancy; certainly there will have to be a little retouching. Send us a print, say, on rough bromide paper, and we will willingly advise you further.

G. B. H.—Air-space lenses require more careful shading from strong direct light, but the definition they give is equal to that of other lenses, often more critical. Some types do not work well with small stops—e.g., at  $f/32$ , but that would not apply at  $f/11$ . We suggest you send us a print or two showing the specific complaint.

LANTERN.—The illumination is very even, equal to a condenser, but not as powerful as a strong direct light, such as the arc or even incandescent gas.

B. DOS SANTOS LEITAS (Lisbon).—(1) We have seen only a working model of the camera. We cannot say more until the finished instrument reaches us for review. We should say one or other of the leading makes now on the market should meet all your wants. (2) Certainly the process is most practical. It is largely used in this country, particularly for transparencies. The makers also supply materials for prints on paper.

REFLECTORS AND BACKGROUNDS.—(1) What material is generally used in reflecting screens—muslin or calico? (2) I have some flatted oil backgrounds. The paint has cracked with rolling up on roller. How can I restore them?—SCREENS.

(1) For reflectors, white or pale blue calico is what is usually employed. For diffusing screens thin white muslin is the proper thing to use. (2) We are afraid that nothing can be done. It is a very useful thing for flatted oil backgrounds to crack in the way described, unless they were painted over distemper ones. Possibly this may be the case in this instance.

COPYRIGHT.—I have had given to me a print of a prize fighter. The name of the photographer is at foot, but it is not marked copyright. Can I copy it for my customer and supply him with prints to sell? I myself do not wish to make any use of the photographs, only to copy it and supply prints in the usual way.—E. B.

If there is no copyright in the picture you are, of course, at liberty to copy it. It is not necessary that a copyright picture should be marked as "copyright." It is most likely that with such a picture a copyright in it would be registered. The only way to ascertain that will be to search the register at Stationers' Hall.

BACKGROUNDS.—Will you kindly inform me what ingredients and quantities are required for painting distemper backgrounds?—J. F. H.

The ingredients used in making distemper backgrounds are common size, whiting, lampblack, or other dark pigment. It is impossible to give quantities, as they must necessarily depend upon the colour or tint desired. If our correspondent will refer to page 82 of our last volume he will see full practical instructions for making distemper backgrounds.

FAILURE TO GIVE REFERENCE.—Receptionist and retoucher wants to know what she can do. Her late employer does not answer any letters that are written to him with regards to her reference. She was with him ten months. She does not know of any reason why he should not, and it is getting quite a serious matter to her, as she is entirely dependent on herself to get her living.—M. L.

We do not see that our correspondent can do anything, as an employer is not compelled to give a late employee a reference unless he chooses. In this case it may be simply negligence on his part. We should advise "M. L." to write him a polite note and point out that his omission to reply is doing her an injury by preventing her from obtaining employment.

N. O. D.—Illustrations Bureau, Whitefriars Street, E.C. (office of the "Daily Mirror").

2.—We advise you to apply to Mr. P. L. Thornton, 74, Fulham Park Mansions, S.W., who, we should say, would put you in the way of obtaining what you require.

G. LAURENS.—Jacks and Co., Glasshouse Street, London, W.; Fradelle and Young, Regent Street; or F. A. Bridge, East Loage, Dalston Lane, N.E.

H. L. A. F. (Finsbury Park).—The only solution which can be recommended is that for the Kallitype process. Formulae and other

directions are given in the "Almanac" for the current year, page 832; or we may refer you to the "B.J." for February 8, 1907, in which an article by a well-known worker of the process appears (p. 96).

**STEREOSCOPIC PHOTOGRAPHY.**—Could you kindly inform me if there is any inexpensive text-book on stereoscopic photography, and if so, the title and name of the publisher?—N. W. FAIRBROTHER.

There is no really good book on stereoscopic work. We advise you to get No. 5 of the "Photo Miniature," which is on stereoscopic photography, and the translation of a work by Drouin, in each case from Messrs. Dawbarn and Ward.

**PHOTOGRAPHER AND SITTER.**—(1) How far is a professional photographer justified in making use of his sitters' photographs by making a public exhibition of them (of course, in his studio window)? (2) Does he leave himself open to legal prosecution for damages by a sitter if he or she sees his or her photograph in the window of the studio where the photograph was taken?—TROPICS.

(1) A photographer has no legal right to exhibit photographs (or, rather, duplicates of photographs), for which he has been paid. (2) He does, unless he has obtained the sitter's consent.

**ELECTRIC CURRENT.**—Will you please inform me if photographers using mercury and arc lights for portraiture are charged by the power or ordinary rates, as I am charged by the latter 5d. per unit, and was given to understand by the makers the charge would be by the former?—ELECTRIC.

It is usual for electric supply companies to charge photographers by the power rate, certainly in the case of consumption during the day time.

**LEASE QUERY.**—I should be extremely obliged if you could advise me upon the following matter. Some few years ago I opened a photographic business in small premises. My premises were a small portion of a larger business premises. The occupier of the business premises is my landlord. When I took over my portion the occupier of the whole premises told me that he had a lease of some seventeen or eighteen years to run, and that he would grant me a lease for seven years. The lease was accordingly made out, duly signed by us both, and stamped, each of us having our own half or portion. My landlord, the occupier, used to live over the business part of the premises, but has lately removed, and it has just come to my ears that he is going to give up the premises very shortly. This, I understand, he can do, as his lease was a terminable one at different periods. I would like to know if he can do this without coming to some arrangement with me. There was nothing said of this when he granted me my seven-years' lease, and I have some four years of this to run. Would the superior landlord turn me out of my portion, and, if so, have I any claim against my landlord for disturbance of my business, which would be very serious? My lease contains the usual clauses, that I am to have free and undisturbed possession as long as rent is duly paid from the lessor, his executors, or assignees, etc., etc. I may say my landlord tried to sell, and failed, and this is why he is going to give up the premises.

If you have to leave the premises before the end of the term of the lease granted to you, you have good cause of action for damages against your landlord. He is held by the terms of the lease he granted to you, and if he is not able to fulfil them he will have to give you compensation. The superior landlord has nothing to do with you, as you are not his tenant. If he takes possession of the premises you will have to go unless you can make an arrangement with him that you remain. Possibly you may be able to do that. Anyhow, you have cause of action against your landlord for not giving you undisturbed possession of the portion you rent from him.

**MATERIAL FOR BACKGROUNDS.**—Will you kindly let us know where we can obtain a fairly stout canvas for painting backgrounds in flatted oils, also material (cream colour) used for backgrounds (not painted)?—WILLIS.

The best material for backgrounds is unbleached sheeting. It is sold by all large drapers and upholsterers. It may be had in different widths up to about nine feet wide. We do not understand the query "cream colour not painted." We know of no such fabric.

**COPYRIGHT.**—Messrs. A. invite the Rev. — to sit, which he does. They then present him four complimentary copies. Upon receiv-

ing these he orders a dozen of them, for which he pays. We copy his photograph (with his permission) and publish in form of postcards, or would such a proceeding be actionable?—MARLBOROUGH.

The sole right to copy the photograph belongs to Messrs. A. D. ORBEEL.—The Chief Inspector is B. A. Whitelegge, C.B., R.O. Office, Whitehall, London, S.W.

W. E. HOLLIDAY.—The camera you mention may be obtained from A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, London, E.C.

WOGHLI.—Carey Lea's papers on the silver salts were reprinted in the "B.J. Almanac" for 1902, p. 312.

HYPO.—The best materials are the glossy-drying colours sold by large dealers—e.g., Fallowfield, Houghtons, Kodak, or Marion.

A. NIEMOLSKI.—The Tress Company, 4, Rathbone Place, London, W.C.

F. W. JEFF.—Billcliff's Camera Works, Manchester, S.W., their list.

J. BACON AND SONS.—So far as we know, the powder is not on market. The "Agfa" flash-powder, as the article mentions, resembles it rather closely. No doubt a chemical firm, such as Griffin's, would prepare the mixture for you.

THE FUNERAL of the late Mr. A. Horsley Hinton took place Saturday last at the City of London Cemetery, Little Ilford. Among those present were Messrs. H. Snowden Ward, F. J. Mortimer, Brookes, A. H. Blake, G. E. Brown, L. J. Bolton, F. A. Briggs, S. G. Kimber, Reginald Craigie, C. Winter (Imperial Dry-plate Company), A. W. Tipp (Thornton-Pickard Company), and several members of the staff of Hazell, Watson, and Viney. Messrs. J. W. P. Rawlins, Alex. Keighley, Percy G. R. Wright, and W. Hazell, sen., were among the mourners.

Tributes to the memory of Mr. Hinton in the form of flowers were sent by Mrs. A. Horsley Hinton, Miss Evelyn Rawlins, Mrs. Gould, Mr. and Mrs. E. Clarke, Mr. and Mrs. James Musset, Mr. and Mrs. Gould and Mr. Tayle, Mr. and Mrs. Frank Maud, Mr. and Mrs. Leonard Clarke, Mr. and Mrs. John Rolfe, Miss and Mr. E. Clarke, Mr. and Mrs. J. W. Palmer Rawlins, Mrs. Kitchin family, Mr. and Mrs. S. Booth, Mr. and Mrs. F. Blott, Mr. Mrs. Bennett, Mr. and Mrs. Alex. Keighley, Mr. and Mrs. H. Hunt (London), Mr. and Mrs. Arthur Rawlins, Mrs. W. Warren, Mr. and Mrs. Goldby, Master Lyster Goldby, Mrs. C. and family, Mr. and Mrs. Arthur Alger, Mr. and Mrs. G. Walton, Mr. and Mrs. George Davison, Mr. and Mrs. Russell, Hunt and family (Reading), Mr. and Mrs. Sharples, Master Sharples, Mr. and Mrs. Rowe, Dr. and Mrs. Acworth, Mrs. L. Miss Claire Cameron, Miss Kitching and Mr. B. Hicks, Mr. Mrs. Walter Crane, Mr. Charles Houghton, Mrs. Varley and G. Kirkland, The Maids, Hazell, Watson, and Viney, "Amateur Photographer" staff, Southampton Camera Club, British Journal of Photography, "The Photographic News," members of The Linked Ring, East Sussex Art Club, council of Park Photographic Society, members Bowes Park Photographic Society, Royal Photographic Society, Scottish Federation, Lake Wight Photographic Society, Birmingham Photographic Society, Liverpool Photographic Association.

\* \* NOTICE TO ADVERTISERS.—Blocks and copy are received only to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

remarkable invention by Professor Lippmann is described by Paris correspondent. Professor Lippmann has devised and brought to a semi-practical stage a method of preparing photographs reproducing the relief of nature without the aid of a camera taking and of a stereoscope for viewing. (P. 192.)

Further discussion of the markings (white outlines round objects) sometimes found in negatives is provided by some on p. 190, and by an article by Mr. A. Mackie on p. 193.

Practical hints on the method of gold toning a sulphide-print have been published by an American worker. (P. 194.)

C. Welborne Piper, in a paper on the nature of the photographic image, further discusses some of the interesting points raised by Mr. Blake Smith. (P. 195.)

The practice of professional photography and the sulphide toning of bromide prints occupy our correspondence columns. (P. 205.)

A practical hint on while-you-wait photography appears on p. 198.

An exhibition of photographs by Baron de Meyer and Mr. A. L. Brown opens on Monday next at the Goupil Gallery, 5, Regent Street. (P. 203.)

Pictorial photography is to form a section of the forthcoming Franco-British Exhibition. The collection, to be formed by invitation, is in the hands of Mr. J. C. S. Mummery and Mr. Reginald Craigie.

An exhibition of photographs of the "Orient," by Mr. H. G. Ponting, F.R.G.S., will open at the "B.J." house next week.

We publish a photograph and a brief account of the newly appointed professor of photography at Dresden, Dr R. Luther. (P. 198.)

A commendable feature of photographic life in Germany is the photographic exhibition, to which we allude on p. 191.

## EX CATHEDRA.

### The "B.J." Colonial Number.

Our issue of the 27th inst. of the present month will be a special one in several respects. Appropriately to the time of year—the opening of the photographic season—we shall review a number of new goods appearing for the first time on the market. We shall commence one or two new features of special interest to our readers both at home and abroad, whilst those of the latter class in all parts of the world will be brought into touch with the home country by several articles dealing with existing conditions in photography in this country. The issue will be enlarged in order to find room for this additional programme. Lastly, a copy will be posted immediately on publication to photographers in the colonies and in all parts of the world from a list which we have prepared and revised within the past twelve months. This directory of colonial and other professionals and dealers is probably second to none in point of numbers and accuracy, yet it does not include photographers who are known to be already subscribers to the BRITISH JOURNAL, but only those who heretofore, so far as we can judge, have not been directly approached by a photographic journal. The "B.J." of March 27, it is believed, will be the first to bring this large and important body of buyers into touch with English houses.

\* \* \*

### Pictorial Photography at the Franco-British Exhibition.

The Executive Committee of the Franco-British Exhibition have decided to include, in addition to an important collection of paintings and sculpture, a section devoted to British pictorial photography. For this purpose suitable, though somewhat limited, accommodation has been provided. A special committee to organise this section has been appointed, consisting of Mr. J. C. S. Mummery, P.R.P.S., and Mr. Reginald Craigie, with Mr. Ferdinand J. Spielmann as Honorary Secretary. The collection of prints, which it is hoped and intended shall be representative of the best work of recent years, will be made by invitation only.

\* \* \*

### Photographs of the "Orient."

We are glad to be able to announce that within a few days there will be opened at the "little gallery" at the house of the "B.J." in Wellington Street an exhibition of photographs of the "Orient," by Mr. H. G. Ponting, F.R.G.S. During the past five years Mr. Ponting has travelled over nearly every country in the East, and his camera has borne evidence to his use of it in Japan, China, Korea, Burmah, and India. Mr. Ponting went through the Russo-Japanese War, and when some months after its conclusion he arrived in London via the Trans-Siberian

Railway, we were, we believe, among the first to see a collection of his photographs. A number of these we are now able to show, thanks to the courtesy of Messrs. Raines and Co., who have prepared and framed the enlargements. The exhibition will be quite distinct from others we have held, but the collection will possess one or two features about which we shall be able to say more in a week's time.

#### White Markings in Tank Development.

In a leader on "White Outlines Round Dark Objects in Prints from Dry Plate Negatives" published in our issue of February 28, we described some very curious modifications of these markings on some negatives submitted by a correspondent. These effects took the form of white streamers ascending from every dark object in the view. We now hear that we were correct in assuming that the streamers were produced vertically during the tank development, and our correspondent is of the opinion that the particular plates were inverted in the tank so that the marks grew downwards. It appears, however, that the developer was not quite still. Every ten minutes in the course of thirty minutes' development the rack containing the plates was moved up and down briskly to stir up the developer. Consideration of all the conditions rather inclines us to the belief that this vertical movement of the plates may have been the chief cause of the marks. In a perfectly still solution the fresh developer would probably have diffused too slowly to produce such long streamers. The white line might have been even more emphasised, but there is no apparent reason why the fresh developer should ascend or descend in a long, straight line across the plate. The vertical lifting of the plates seems to afford the needed explanation. Our correspondent wishes to know how to avoid the effect in future, but it is rather difficult to advise on this point. One contributory cause may be the too near spacing of the plates in the tank, and, in any case, a widely spaced rack is advisable. The immediate cause apparently being the vertical movement of the plates at long intervals, the effect might be avoided either by not moving them at all, or by moving them at more frequent intervals. In any case, the conditions of tank development are not favourable to perfectly even development, and we doubt if pyro soda is at all the best developer to use. When used in a dish rocking is always advisable, hence it seems an unsuitable developer for use in a tank. We should prefer either rodinal mixed with distilled or boiled water, or glycin. The ideal developer is evidently the one that works most evenly without being kept in motion.

#### "Mackie's" Mark.

As stated in Mr. Mackie's article in this issue on the white line phenomenon, it is a curious fact that the mark is generally rare, and yet so common with certain individuals. We have never seen it on any of our own negatives, which have all been developed in dishes that have not always been kept in motion, but we have frequently seen it on other people's negatives, on roll films as well as on glass plates. Its possible connection with halation is rather difficult to see, and we are much more inclined to favour the development theory than any other. Indeed, the truth of this, in at least some cases, is fairly well proved by the case we last commented upon, in which the white line was drawn out into long streams by lifting the plate in the developing tank. Another very notable case of a line (without streamers) brought to our notice was on a roll film developed in the early pattern of the Kodak developing machine, with which the film was kept in continual motion. The conditions in this machine are rather peculiar. The film is certainly pulled through the deve-

loper, but what kind of movement is imparted to the developer it is a little difficult to say. The films are, however, fairly close together, as they are in a good many ordinary tanks, but we are quite unable to say whether this is the essential condition for the production of "Mackie's Mark." The instance he mentions of the mark being seen on a Daguerreotype is new to us, and certainly we should not have anticipated it. On consideration, however, we are very much inclined to think it can be accounted for in a very similar fashion. It is not difficult to conceive an overlapping over the lights of the vapour that accumulated under the shadows, and a consequent more rapid development just on the borders of the shadows. Though the action of the vapour is altogether different from that of an alkaline developer, still it is used up by the image, and can be replaced by fresh vapour from the shadows as well as by fresh vapour rising up from the bottom.

#### Photographers' Fires in London.

From the annual report of the Chief Officer of the London Fire Brigade issued on Saturday, it appears that a fire occurred at a cinematograph exhibition during 1907 due to defective electric circuit. Five outbreaks occurred at photographers' premises. The causes of the outbreaks are distributed as follows:—Due to defective electric current 1, gasfitters at work 1, hot ashes 1, light thrown down 1, unknown 1. The total number of fires in Metropolitan during the twelve months was 3,320, of which 975 occurred in private houses. Licensed houses headed list of trades with 84 fires, cabinet-makers coming next with 47, and tailors and confectioners tying for third place with 42.

#### The Cut-Out Mount.

A contemporary makes some severe remarks on the use of the "cut mount," stating that its "proper place is round a print which simply records what is on a negative of one of the standard sizes for reference purposes of some kind or another." This is severe, but rather ambiguous, and probably it is the slip-in mount that is referred to, not what is commonly known as a cut-out. For our own part the genuine cut-out mount, which need not conform to standard sizes at all, can have much said in its favour. As regards appearance the recessed effect it gives is often a most desirable one, while practically it affords great protection to a print with a delicate, easily-damaged surface. In addition to this, it is a type of mounting that is easy to carry out. With the cut-out mount it is a comparatively simple matter to avoid that most objectionable effect in picture work, the effect of the picture standing out in front of the mount. With some of the more popular methods of mounting it is very easy to give an unpleasant raised panel effect. A raised panel is a good and very suitable plan for a piece of decorative work, but if more than mere decoration is aimed at it is just the situation to avoid. A picture, properly so called, can never be seen to the full advantage unless the effect of the subject being belied by the frame is secured. Putting the picture in a shallow recess, and literally behind the mount, is one of the easiest ways of producing this effect, provided, of course, the mount is of the right tone.

#### Cutting Out-Outs.

As regards cutting the opening in the mount this is a very simple operation for an amateur if he uses a bevelled ruler and a flat-bladed sharp-pointed knife ground on one side only. With a professional mountcutter's knife and rule it is a difficult task for a beginner, but the bevelled rule and flat blade clear away all difficulties. The print should be mounted on a large board the full size of the mount, or larger,

cut-out mount should then be fixed down over the print with some strong mountant. This is a most permanent and substantial kind of mounting, and it is a very valuable method for prints that are not to be framed. Mounted in this way even oil prints can be stacked away, one over the other, without the least fear of damage.

\* \* \*

**Improved** Mr. R. A. Houstoun, of Glasgow University has just described an improvement in this instrument by which one of the prisms, the Glan-  
**finer** Thompson polariser, is done away with. In the  
**electro-** existing form there are two prisms, the above-mentioned,  
**tometer.** which polarises rectilinearly the light beam, seen at  
top of the eye-piece, and another which reflects natural  
light to the lower half of the eye-piece. Mr. Houstoun's  
improvement consists in cutting the prism at the eye-piece  
into an isosceles triangle, and cementing to its base an Iceland  
spar prism of particular shape. The two beams of light  
are both polarised at right angles to one another. The  
ocular slit is only seven millimetres high, but in spite of  
this small aperture it is stated that there is no difficulty  
in practice in comparing the two spectra.

\* \* \*

**Elementary** Opinions differ a great deal as to the  
**Optics.** value of so-called "elementary" dissertations upon optics, and probably the chief reason for their being  
flatly condemned by some is the fact that they are often so very inaccurate. Optics form a rather profound  
branch of science, but, still, there are many useful optical facts that can be explained accurately  
in simple language. Unfortunately, however, some writers do not seem to be capable of  
employing simple language without descending into striking  
inaccuracies, and an article in an American temporary affords some striking instances of this. The  
author explains how flatness of field can be tested by photographing  
a newspaper tacked to a wall, and then breaks into the remarkable statement that the faster the lens  
smaller is the angle that it will cover with sharp focus, the slower  
the lens the greater is the angle. In view of what modern rapid  
anastigmats will do this is startling, though rather less so than the next statement concerning the second  
test. This second test is made by focussing on a building as sharply  
as possible with full aperture. We are then told to stop down to  $f/16$  and expose a plate,  
after which we are to cover the stop opening by sticking a disc of paper  
on the lens, and then open out to full aperture and expose again through  
the annular aperture. The results are equally sharp the lens has a flat field,  
they are not it has a curved field, which is the most refreshing piece of  
information we have come across for some time! Later in the same article we see a test  
for flare spot with instructions to look for an effect that will not flare  
spot at all; and yet again, an experiment that illustrates the want of depth  
is employed for distortion! Unworkable tests for chromatic aberration and  
anastigmatism are also described, and, altogether, the paper perhaps, the best  
example we have seen of elementary optics in its most inaccurate form.

\* \* \*

**Camera** We live and learn. The lay process has  
**Costly** astonished us now and again with marvels of photography, but of late the  
**Photography.** records have been those of the price paid for photographic work more  
often than of the achievements themselves. Last week we read of a  
photographer who "has just perished a camera whereby he is prepared to take likenesses at  
£200 a piece." An inevitable accessory which, no doubt,

the investor will announce ere long is a machine for procuring the sitters and getting the money from them. However, the new camera can be induced to produce a print at £40 and even as cheaply as £20. Apparently the article is a highly coloured account of somebody who is taking life-size portraits direct, though it is difficult to extricate a possible fact from its tangled narrative.

\* \* \*

**Distortion of** The question of stability of photographic  
**Photographic** films is of so great importance to all who  
**Films.** use them for any work involving measurements of precision that any investigation into the possible changes is of general importance. It is therefore interesting to see stated by Mr. C. P. Butler in "Knowledge" that Mr. F. Schlesinger has been examining numerous plates taken for standard star charting purposes. It was very necessary to find out whether the processes of development, washing, etc., left the films in the same condition as when exposed. Mr. Schlesinger's conclusion is that whatever error there may be due to distortion of the film is much smaller than the bisection error of the best star images, being not more than about 1-1000 mm. for the particular plates employed.

## STUDENTS' PHOTOGRAPHIC EXHIBITIONS.

It would not be an easy task to enumerate all the many and varied activities of the famous Technical High School of Charlottenburg, which has for many years been looked upon as a model of what a high school ought to be. Almost all subjects of a technical nature are represented there, and have their professors or teachers. As is well known, photography is also represented in the Technical High School, though, until now, the subject has only been treated in a half-hearted manner. This negligence of a technical and art-industry that has proved so important for Germany is the subject of frequent complaint, and there is an agitation to make of it a distinct subject for study, having its own particular teachers, instead of treating it as a side issue of the chemical department, to be experimented with and treated spasmodically according to the whim of one or other professor, as is at present the case. There is every possibility that Charlottenburg will soon make amends for this neglect by following the example set by the Dresden Technical High School and introduce a professorship of photography.

Our present interest for photographers in Charlottenburg is the photographic exhibition held by the students there. A glance at the exhibits proves not only the enthusiasm for photography already manifest among the students, but also the fact that the professor, when he is appointed, will have sufficient excellent material to begin with. The present is the fourth photographic exhibition which the students have held, and it seems to be growing greatly in popularity among them. Among the exhibits are many photographs of real merit, and one can distinguish the work of the artist as well as the more technical work of the engineer. There are also some good portraits and landscapes.

The idea of a students' photographic exhibition is not altogether new in Germany, we fancy, nor is it one of the things we have yet to learn from Charlottenburg, still the example cannot be too strongly recommended to our own students and the responsible authorities in the various schools, colleges, and technical schools. In Germany it has been found an excellent means of interesting the students during the long holidays, and of keeping them usefully employed. Though the work may represent the lighter side of student life, as it may be called, being more

of a pastime in contrast to the more serious object of their work and studies, it has, nevertheless, been found to foster and to encourage that spirit of friendly rivalry and competition with which German professors endeavour to imbue their students. Then, too, much might be said of its

social aspects, the opportunities it offers for adding interest to the walking tours which German students make periodically, and of the interest which it gives them in a multitude of subjects which may not be altogether immediately associated with their particular studies.

## STEREOSCOPIC PHOTOGRAPHS MADE WITHOUT A CAMERA AND VIEWED WITHOUT A STEREOSCOPE.

[The following article from our Paris correspondent describes very probably have important developments. We are not sure Lippman has brought it to a practical experimental stage that are clearly described in the article, but it has one other advantage that our correspondent has omitted to point out. In addition to producing stereoscopic effect on a single plate images with absolutely unlimited depth of field, all objects at the same time. It will be seen from the article that the only one of a kind that will probably be overcome; hence it is not very long.—Eps. "B.J."]

ONE might almost say nowadays concerning photographic departures, "Ex Gallia semper aliquid novi." After the telec photographic system of Belin and Lumière's multiple grain-screen colour-plate, we have now from Professor Lippmann—of interferential colour-photography fame—a new method of obtaining stereoscopic effects—and more besides. The nearest analogy to the system proposed by the eminent French savant is to be found in the eyes of certain insects, which, as is well known, are multiple, consisting of an assemblage of minute lenses, each of which forms an image of the object viewed on the corresponding retina. A good microphotograph of a scarab's eye, and the multiple images formed, is given by Mr. A. E. Smith in the "Process Year-Book."

It is by using a plate formed somewhat on these lines that M. Lippmann proposes to take positives on glass giving directly and without an objective the sensation of relief peculiar to stereoscopic views. Not only is this relief more exact, but the perspective changes according to the angle from which the plate is viewed, an approximation to nature not hitherto attainable

Fig. 1.

by any instrument. And all this on one plate exposed in a simple dark-slide to the landscape or object without intervention of objective or camera.

The arrangement by which these remarkable results are secured is as follows:—A film of celluloid or collodion, with a species of honeycomb structure, is prepared. Before coating with the emulsion, whilst still warm or unset, imagine it impressed by a plate so hollowed *in petto* as to cover the film with a relief of small hemispherical surfaces. This is done for both sides. The anterior hemispheres, intended to act as lenses, have a smaller radius of curvature than the posterior ones, which are covered with a sensitive emulsion. Each cell of the latter should receive an image formed by one of the small lenses of the anterior surface. Fig. 1 shows an enlarged section of such a film.

It is necessary that each of the corresponding segments should have the same curvature, and that the relation between the radii of curvature of the front and back hemispheres be equal to  $n-1$ , where  $n$  is the index of refraction of the medium, e.g. collodion. The front hemispheres form a series of lenses, the back ones, the photographic plate, the curvature of which ensures an exact focus over its entire surface, just as in spectrographs

a highly ingenious invention of Professor Lippmann that we think the idea is absolutely new, but it is evident that Professor Lippmann certainly never reached before. The details of the invention are not given, but our correspondent has omitted to point out that without the aid of camera or lens it permits the production of images beyond a microscopic distance from the plate being in focus. The material difficulty in the way is a manufacturing one, and it is too much to hope that the new plates will be available before

plates and films are bent to the curvature of a particular gratings. The whole cell acts as a small camera, comprising lens, camera and film. The intervening wall between any two cells has to be rendered opaque so that very oblique rays cannot pass from one cell to another. The actual film thus consists of a layer of these cells juxtaposed, and all identical in size and position.

We may now consider the formation of an image of any object, and the reproduction of the same obtained when the plate is viewed.

As the focal length of each little lens is only a fraction of a millimetre, all objects beyond a slight distance will be in focus. Each forms on its corresponding section of the sensitive film a microscopic image of the landscape, which varies slightly in

Fig. 2.

point to point as the angle of incidence changes. We think that, therefore, a large array of images of the object, just as the multiple eye of a beetle forms numerous images. Suppose the film developed to a positive and viewed as a transparency from the side L. We shall not see the juxtaposed array of images which might be expected, because (by virtue of its accommodation) the eye only perceives one point of each image, and the assemblage of all these points forms a complete image the size of the plate. As the position of each point perceived varies according to the angle from which the plate is viewed, we can follow the panorama across the plate exactly as in regarding the same scene in nature from different points of view. Moreover the reproduction will be in perfect relief, giving exactly the same sense of perspective.

Consider in Fig. 2 any point  $a$  in one of the small images. The rays issuing from  $a$  are all parallel, since by construction  $a$  is at the focus of the lens. The eye at  $O$  will perceive  $a$  as if coming from the point  $a$  projected to infinity in the direction of  $AOa$ . Further, the direction of the emergent bundle is exact

that of the incident bundle which during exposure was concentrated on *a*. Hence the eye perceives the photographic image of *A* as though projected in space in the direction joining the optical centre of the eye to the point *A*. The same holds for any other point *B*. The directions being preserved, the angles and apparent magnitudes also remain the same. It follows that the real images thus formed occupy in space, with respect to the system of cells and to one another, the same position as the original points, forming images optically equivalent and in three dimensions to the object reproduced. Through its accommodation the eye will perceive them in the aspect proper to the point of view. This changes with the position of the eye, and as we have two eyes in different positions this imposes the corresponding perspectives, and the condition of sensation of relief is thus obtained without the use of a stereoscope.

The image thus formed is obtained as a negative on development, and is also geometrically reversed. The reversal of the image may be secured by developing to a positive, as with Autochrome plates, or, better, by copying the negative on to a second film placed at an arbitrary distance of some centimetres from the first, contact not being necessary, since the process is only a repetition of the original procedure. This method has the advantage of giving any desired number of positives.

In order that the multiple images may give only one impression to the eye, the cells must be sufficiently small and near together, the condition being that the distance between two cells be less than the pupillar opening.

In any given position the image is limited by the edges of the plate, like a landscape viewed through a window. But on moving the head other objects will appear in the same limits, so that one can perceive a complete panorama pass over the plate.

The remarkable capacity for seeing a series of views in succession on the same plate arises from the curvature of the component elements. When viewed directly, the image seen is the summation of elements, each of which lies at the centre of the small cellular elements scattered over the plate. If regarded obliquely the summation extends over elements present in the lateral portions of the cells. If the aperture of these is 120 deg. it follows that 120 deg. of the landscape is included, this being comprised in each elemental cellular image. If we imagine the film bent to a cylinder, one could sweep 360 deg., and with ellipsoidal or spheroidal surfaces take in the heavens and the earth as well as the horizon, thus making the resemblance to certain insects' eyes more complete.

Professor Lippmann comments on the difficulty in realising completely the optical conditions necessary for the perfect clearness of each cellular image. His present results are still very imperfect; the "honeycombing" plates were prepared by hand by a mechanic, and the intervening cell walls spotted out by hand with a fine brush. Owing to the minute dimensions, the exact realisation of the condition that the ratio of the radii of curvature of the two surfaces be equal to  $n-1$  is difficult. It may be possible to use spherules of glass, ground to the necessary surfaces and set in collodion. If a glass could be obtained, say by a mixture of molybdates or tungstates of lead, with an index equal to 2, the parallel rays which it receives would converge on the posterior surface. Such a sphere, covered on one half with the sensitive emulsion, would constitute the simplest conceivable form of the elemental cells or dark chambers. One can only hope that the technical difficulties in the way of Professor Lippmann's ingenious discovery will be overcome.

## WHITE OUTLINES ROUND DARK OBJECTS IN PHOTOGRAPHS.

I was much interested in the article on this subject in last week's "B.J." for two reasons. Some years ago I drew attention to the phenomenon referred to at one of the meetings of the Photographic Club, the example being in a lantern-slide then being shown on the screen, and was promptly told that the effect was merely an optical illusion. On the following evening I brought up the subject at the meeting of the London and Provincial Association with the same result. At subsequent meetings at both places I was able to show without difficulty that it was not an illusion at all, but that many examples existed of prints, transparencies, and negatives where there was this white outline round a dark object shown against a background of light half-tone. The subject cropped up for discussion several times in both places, and the phenomenon itself became known as the "Mackie" line—I heard it referred to thus only a month or so ago. Finally there was a general agreement that the cause was that given in last week's article, namely, that the oxidised developer over the light tone is replenished from the unused developer in contact with the part of the film representing the dark object; hence development in the light tone proceeds more rapidly in the immediate neighbourhood of the dark object. That explanation thoroughly satisfied me at the time.

My other reason for interest in the article is the reference to white streamers proceeding in one direction from dark objects in plates developed by the stand method. Although I have never had this experience on negatives developed by myself, a friend—a professional photographer, to whom I had recommended stand development, and who could not succeed in making the system answer his purpose—showed me several negatives on which this defect was present to an extent that amazed me, and subsequently, on looking over a number of negatives by

another professional photographer who has used the stand method of development for a considerable period successfully, I found a few showing a trace, but a trace only, of the same defect. Whether the streamer proceeded from the dark part of the negative upwards or downwards as the plate stood in the tank I was not able to ascertain. Now, it appeared clear to me that the cause of this encroachment was similar to that referred to in connection with the white line; that seems the obvious conclusion to come to: but as we know that Nature always does the same thing under the same circumstances, the question arises, what are the exceptional circumstances that bring this effect about once or so in a way in the development of thousands of plates, or with one operator only among hundreds? I suppose the difficulty of tracing the cause is the usual one when photographic failures are being diagnosed. The operator can say precisely all the things he did which could not affect the matter, but has neglected to notice those which could affect it; otherwise he could diagnose the case for himself. As I have never experienced the occurrence myself, and could discover no determining cause from those who had, whatever I think is necessarily in the nature of guesswork, but I fancy the solution of the problem may be found to be something to do with change of temperature of the developer while development is proceeding. For instance, with a developer at a higher temperature than the air of the dark-room, the cooling of the developer at the top and sides might create a circulation in which there was an upward and a downward stream, or with a tank of cold developer placed on a warm table a similar effect might occur. The amount of space between the plates also may be a factor. Insufficient mixing of the developer I do not think is likely to be the cause. That, it seems to me, might cause irregular development, a further stage

of development on that part of the plate at the bottom of the tank, perhaps, but not this regular stream which appears on negatives otherwise quite perfect.

Since this article was set up in type I have been furnished with information from the author of the query that the streamer effect only occurred in a few cases out of a large number of negatives—about 250—developed under what appeared like precisely similar circumstances, and it was surmised that the effect was only produced when the skies were downward in the tank. According to the circulation theory, with a downward vertical current in the developer the skies would have to be at the bottom of the tank, and with an upward vertical current the skies would have to be at the top to produce the effect. But with warm solution in a cold tank one would expect to find a downward current round the sides of the tank and an upward current in the central part. Under these conditions adjacent plates in the central grooves, one sky upward and the other sky downward, should show both the streamers, the one towards the middle of the plate, but not at the two ends, the other at the ends, but not in the middle. If such examples can be produced the soundness of the theory will be established.

To return to the white line. I had a very fine specimen of daguerreotypy given me a few days ago. It is before me as I write. It represents a gentleman in a black coat seated before a background of medium tint. The white line is unmistakable in some places where the background abuts on the deepest shadows in the coat. In this case there was no developer to flow. The picture was developed with a vapour, so that with regard to the white line in daguerreotypy the problem requires another solution.

In all photographic problems of these kinds there is an element that requires to be taken into consideration, and that is personal

equation. Is it not the fact that while one photographer is daily attacking all kinds of outdoor and indoor subjects without thinking of backing a plate, except when the nature of the subject renders that course absolutely necessary, and yet producing negatives free from halation, another quite as skilful a photographer, as far as his results are concerned, will have to use backed plates to photograph even the knocker on a street-door? I dare say one could look over hundreds of photographs before finding a good example of the white line, but when that example is found probably it will also be found that one has only to look over the work of the same photographer to find plenty more equally good. It is quite possible that the white line and halation are more closely connected than one might suspect. Not that the cause is the same, but that whether the phenomena are of frequent occurrence or not is a matter arising in a great measure from the methods or personal equation of the manipulator. The halation will also be a white-line. Perhaps some philosopher in days to come will investigate and let us know why it is that often the most careful student of photographic science, the most rigorous observer of all the rules and regulations, laws and by-laws of the text-books, with every aid to success at his disposal that money can buy, and careful and orderly in his procedure, will in practice make negatives always over or under or too or not enough something, with a plentiful crop of just the kind of interesting matters for investigation that led to this article, while an apparently most careless hustler, with apparatus all that apparatus should not be, with a pinch of this and a drop or two of that in a dirty measure, a dirty dish, and a dark-room that would give a tidy man a fit to behold, will produce results almost perfect of their kind. Until this question is properly investigated, let us assume that the answer is, it is due to the possession or lack of the photographic instinct.

ALEXANDER MACKIE.

## RED TONES ON SULPHIDE-TONED BROMIDES.

[The following notes, on a method on which little has been written, are from our Boston contemporary, the "Photo-Era." The writer, Mr. George H. Scheer, evidently thinks well of this process, which, we may point out, was first recommended by Mr. A. H. Avery in "The Photogram" for 1904, and has since been worked and demonstrated very successfully by Messrs. Wellington and Ward. We regard it as too lengthy for regular work, but for occasional use it is undoubtedly a useful process.—Eds. "B.J."] ]

By this process we are able to produce on bromide paper a variety of red tones ranging from orange to crimson, the tint depending upon the brand of paper used, the length of exposure and development, and also upon the length of time the toning is allowed to continue. Naturally, a red tone is desirable only in a very limited class of subjects, such as sunrise and sunset views and fire scenes; but the effect of proper toning on these is marvellous, the tones obtained being so realistic that the picture looks more like a painting than a photograph.

It is hardly necessary to state that it is never advisable to carry the toning process so far that the entire image has been converted into red, as the result could not be anything but unnatural and disagreeable in nearly every instance. The charm of the process lies in the double tones obtainable. The toning-bath will act on the lightest tones first, progressively attacking the darker ones. The toning may be stopped at any point, the action of the toner ceasing as soon as the print is removed from the bath, and no further after-treatment is required, the print merely being placed in a tray of running water for about half an hour's washing.

The first step in the process—or, rather, the preliminary step—is the redevelopment of the print. This may be done as above described, but a print toned brown by the hypo-alum method will tone equally well by this process.

Prepare your toning-bath as follows:—Dissolve ten grains of

ammonium sulphocyanide in ten ounces of water (preferably distilled or pure rain-water) and add one grain of gold chloride. The gold chloride is best kept in a stock solution, the strength of the solution being immaterial so long as you know what it is. The stock solution should be made up with distilled water. As soon as your bath is mixed it is ready for use. Pour it into a clean tray—one of porcelain or glass, if available, being the best to use—and immerse the print in the solution. If you have time it is well to rock the tray constantly, as it ensures even toning. After a few minutes the lightest half-tones will begin to assume a light reddish tint, which will deepen gradually, and one after the other the deeper tones will successively take the tone. The rapidity of the toning action depends upon the amount of gold in the bath. With a bath of the strength above given it will take about half an hour to an hour to obtain the tone desired, the deeper the red the longer the time required. The bath becomes exhausted rather quickly and the toning proceeds more and more slowly as the gold is deposited. To accelerate the action it is only necessary to add a little of the gold solution, removing the print from the bath first and thoroughly mixing the solutions before replacing the print in the bath, for otherwise the toning will be uneven. When the desired tone is reached, remove the print from the toning-bath and place in running water for half an hour's washing. If, when the print is toned, you wish to strengthen the tone in any part of the print, this may be

ly accomplished by resorting to local toning. With a cotton swab, soaked with the gold solution, go over the portion of the print you wish to tone while the print is covered with a shallow solution of the toning-bath. After most of the gold solution has been removed, the swab has diffused into the bath the tray may be tilted so as to leave the spot you are working on uncovered, and you can then go over it with the swab until the desired tone is secured.

Generally speaking, prints which have had a comparatively long exposure and short development, and, therefore, take a light brown tone in redeveloping, will assume more or less of an

orange tone in the gold sulphocyanide bath. On the other hand, prints that have had a short exposure and long development, and which come out of the redevelopment having a deep, dark brown, take a purer red tone. In "Royal" paper the red is brick, or chalk-red, while in Platino bromide it is more of a crimson. So you will see that the tone of red which the print will assume is determined almost wholly by the length of exposure in making the print. Long exposure gives yellowish reds, short exposure brick-red and crimson. Determine beforehand what tone you desire to give the print, and you will be able to get it exactly after a little experience. GEORGE H. SCHEER.

## THE NATURE OF PHOTOGRAPHIC IMAGES.

MR. E. BLAKE SMITH's article on the nature of the image in a P.O.P. print was a very valuable and suggestive one, and I naturally find it of great interest, as it in some measure affords confirmation of the theory of re-development put forward by Mr. Carnegie and myself in 1905. At the time we looked upon the facts which we discovered as interesting rather than important, excepting, perhaps, in the case of the re-developed iodide image which proved to possess such covering power as to render the process a valuable method of intensification. One never knows, however, where the numerous by-paths of a piece of photographic research work lead to, and it is never safe to leave them quite unexplored, therefore we recorded such facts as we had time to determine on the chance that later they might be useful. Mr. Blake Smith seems to have been the first to turn them to account, and after carefully reading his paper I am inclined to think that he has made a very good case for his theory concerning the presence of sulphides in the gold-toned P.O.P. print. In connection with this subject there is a point which possibly he has missed. If silver sulphide exists, then, as it is formed in gelatine, it is very likely to be easily soluble in hot water, and as is the brown sulphide image of a sulphide-toned bromide print, this is the case it can be separated quite easily from the other constituents of the P.O.P. image, and its existence can be definitely proved or disproved. If, however, the sulphide forms a lake with silver chloride, as Mr. Blake Smith assumes, of course, it may not be soluble. If it proves to be insoluble in water, while other tests prove the existence of a sulphur compound, then there is strong presumptive evidence in favour of the lake theory.

There are one or two points in connection with the residual silver compounds that we found in various developed images that are worth mention. Even if a fair quantity of such compound is found after the metallic silver has been removed from the image by nitric acid or some other solvent, it does not necessarily follow that that residue is either quite undevelopable or insoluble or "stable" in P.O.P. A portion of it may exist simply because it was protected from the fixing bath by the silver. We found many instances of such protective effects. Notably in the case of images bleached in bichromate solutions, where the silver haloid compound and the chromium compound are mutually protective, as pointed out in our articles in the "Amateur Photographer." This is a matter that must not be overlooked in the analysis of photographic images, for one cannot be quite certain that all the soluble constituents of the image have been removed until the various solvents have been applied several times alternately.

### Intensification by Increase of Bulk of the Image Compound.

As regards the enlargement of the particles being the cause of the greater density produced by re-development, we did not suggest the formation of a "lake," as it appeared to us that the simple increase in bulk was enough to explain the matter. Mr. Blake Smith does not seem to consider it enough, partly on the ground that by bleaching the image we can increase the size of the particles, and yet decrease the covering power. Naturally, this is so because the small black particles are transformed into particles which, though larger, are white and more or less translucent. If, however, only partial development will render them black and opaque, the necessary condition for intensification is secured without the interposition of a

lake. I think the results we obtained with re-developed iodide images prove this. In these experiments we produced strong intensification and quite black images, though the reduced silver was very small in quantity, too small, in fact, to protect the iodide from the action of a fixing bath in which it, or the greater part of it, was readily soluble. So far as we could determine, the bulk of the iodide was just ordinary silver iodide with no peculiar features suggestive of a lake, and we considered that our experiences and tests of the iodine method of intensification fully justified the suggestion that a simple increase in bulk could be productive of intensification. I am therefore not quite in agreement with Mr. Blake Smith's contention that the formation of a lake must be assumed to account for the greater covering power, though at the same time I am strongly of opinion that some such lakes or solid solutions, or whatever we may call them, are formed in greater or lesser quantity in certain conditions. I think the cessation of development at such an early stage proves their existence in the case of bromides and chlorides, though it may not do so in the case of the iodide. In our articles we mentioned one extraordinary form of silver chloride, but we came across and we repeatedly found very intractable compounds that were certainly not ordinary halides. A notable instance was the deposit found on Krystal gaslight plates. Mr. Smith refers to the coloured images formed on such emulsion by prolonged exposures, but the ordinary black image also contains a similar compound in liberal quantity, and his term of "lake" is probably as applicable to it as to the coloured images.

While studying Mr. Blake Smith's paper it occurred to me that there are certain coincidences in the behaviour of various images that may be worth further study.

### The Two Classes of Bleaching Agent.

We have available two classes of bleaching agents. The one class oxidises the image directly and produces a simple silver halo'd salt that cannot be developed without exposure to light, while the other acts upon the image indirectly and produces a complex compound of silver and halogen that is quite readily developable without any exposure. Bromine water is an example of the first bleaching agent, while a mixture of potassium ferricyanide and bromide is an example of the second—a good example because its action and effects have been closely studied and examined. An image bleached in bromine water, if exposed and developed, behaves in practically the same way as an ordinary bromide emulsion dry plate. It can be rendered undevelopable by over-exposure; it develops very slowly and with difficulty if under-exposed, and it cannot be re-developed to its original density unless exposure has been approximately "correct." There can be no doubt that in both cases exposure produces the same light-product or latent image, which product, according to many authorities, may be a lake or solid solution somewhat similar to the lakes described by Mr. Blake Smith.

### Does a Bleacher give a Compound similar to the Latent Image?

The image bleached in the ferricyanide and bromide solution requires no exposure, and too much exposure will render it undevelopable, while without any exposure at all it will develop very rapidly. These facts suggest that it contains a similar compound, or a similar "latent image," to that produced by the exposure to light of simple

silver bromide, but possibly in a larger quantity. If a similar product is formed either by the reducing action of light as silver, bromide, or by the action of an oxidiser on silver in the metallic form, we may expect the second method to produce the larger quantity, seeing that the action of the oxidiser affects the whole particle, while that of light can affect only a small portion of it, and the suggestion that the oxidised particle contains the larger proportion of "latent image" is supported by the fact that it develops more rapidly.

Here we come to the coincident facts referred to. Analysis, after development, shows that an image rendered developable by exposure to light contains only the faintest possible traces of the mysterious lakes under consideration, whereas the image that has been rendered developable by a process of oxidation contains a sufficient quantity to give it greater covering power, and is, in fact, intensified. Thus, in the case where there is every reason to expect a larger quantity of the product that forms the latent image, we also find a larger quantity of the undeveloped "lake."

This at once suggests a possible connection between the latent image and the residual lake, but if we assume the two to be the same, then the logical sequence is rather remarkable.

### A Theory of an Undevelopable Latent Image.

First, we must admit that the latent image, whether produced by light or by chemical action, is itself undevelopable, but that in its presence the immediately adjoining silver bromide becomes developable: this being quite opposed to the general idea that the image, as a whole, is developable, because the latent image is developable.

Second, we must consider reversal to be wrongly so called, and

must look upon it as the simple consequence of the continuing action of light, or of the production of an excess of undevelopable product.

Third, we may look upon development as being an action of catalytic nature, the latent image being the catalyser.

I am not able to say how far such a revolutionary hypothesis will square with other facts that have been ascertained by those who have especially devoted themselves to the study of the latent image, but at any rate, the suggestion that the latent image is undevelopable instead of being developable, offers a very simple explanation of reversal, which is more than some other theories do. It also very fully accounts for the facts observed in connection with re-developable images. It does not offer any obvious explanation of re-reversal, but that is a phenomenon that has always seemed to me to be one of more or less hypothetical nature.

There is yet one more point worth mentioning. If the lake, solution, or latent image formed by the action of certain oxidisers upon silver is the same thing as the light product formed when silver bromide is exposed, then it is possible to prepare the latent image compound in bulk and analyse it. As a matter of fact, the haloid compound formed by the ferricyanide and bromide bath has already been proved to contain an excess of silver (see Mr. D. J. Carnegie's paper in B.J., November 30, 1906), and therefore to be at least analogous to the assumed composition of the image on an exposed plate. It should be easy to separate the undevelopable and developable portions of the compound, and to determine the composition of the former. The results might be interesting, even though they would not definitely prove that the undevelopable lake and the latent image were one and the same thing. C. WELBORNE PIPER.

## SOME QUESTIONS AND ANSWERS RELATING TO COPYRIGHT.

[An Indian reader of the "B.J.," writing as "B. O. J.," from Kathiawar, addresses to us a number of questions as to infringement of copyright which we can better reply to here than in the usual "Answers to Correspondents" column. The replies to our querist's specific inquiries will perhaps be of interest to others than himself, right Act supplies an unmistakable answer to many of the points in the "B.J. Almanac" for 1906 affords an explanatory review of almost equal importance.—Eds., "B.J."]

Is THERE ANY INFRINGEMENT of copyright in each of the following cases?—

A reproduces a copyright photograph by B of C to C's order:

1. On paper or basis different from that used by C.
2. By a different process:
  - (a) Photographic, or
  - (b) Manual, as by drawing or painting in water or oil colours.
3. The reproduction is not an exact facsimile, but (a) faked, (b) retouched, and (c) manipulated so as to produce (1) a different, (2) novel, or (3) better effect.
4. The reproduction is a caricature. Will it make any difference were it not to C's order but to that of the publishers of "Punch" or the like?
5. The reproduction is an enlargement or reduction on bromide, gaslight, or carbon paper, or
  - A, a miniature, (a) plain, (b) hand-painted.
  - B, a stamp photograph with artistic border.

In reply: It is a pity our querist does not make it perfectly plain as to who is the proprietor of the copyright. If C paid for his photograph to be taken, then all the acts mentioned in 1 to 5 can be done by A to C's order, because C is the owner of the copyright. But if B took the photograph without "good or valuable consideration," the copyright is vested in him, and no one except himself has the right to make copies in any shape or form. It matters not whether (1) the paper is different, (2a) the process photographic, or (2b) hand, nor does it matter (3) whether the copy is worked up or improved, or (5) enlarged, reduced, or coloured. So long as it is evidently a copy or colourable imitation it infringes the owner's (i.e., in this case, the author's) rights in it.

4. In the case of caricatures of photographs or other artistic works, we know of no case in point. But, arguing from literary

copyright, a parody of, say, Tennyson's "Charge of the Light Brigade" would not be an infringement of the literary copyright, and apparently, to judge from custom, caricatures of artistic works which are obviously intended to be caricatures are not infringements.

6. Will it make any difference were it not to C's order but of A's own accord to display it as a specimen of his own work and skill in reproduction?

Presuming B to be the owner of the copyright, it would equally be an infringement.

7. A uses a copyright artistic border design or decoration of other work of B, purchased from him, to surround or embellish his own production.

- (a) Where he uses a border negative direct same size.
- (b) Where he makes an enlargement or reduction of border negatives of one size with him for use by him with larger or smaller size prints.

(1) Where such larger or smaller size border negatives are put on the market by the author of the copyright, and

(2) Where they are not, or not available, the stock being exhausted.

A has no right to make a negative from the copyright border design of B, unless the act of purchase is specified, as it is, in such case, to confer a limited right of reproduction. It is immaterial whether the copy is made (a) same size, or (b) enlarged or reduced. If he has the right to copy he can do both; if he has it not, he may do neither.

In the case of border negatives (1) placed on the market, it is understood that positive copies may be made, but it would no doubt be considered an infringement to reproduce and sell exact (i.e., negative) reproductions of the borders. Such provision is an

vious condition of sale, and would not be affected by the fact (2) that particular sizes of the border negatives were out of stock.

8. Where he supplies negatives of prints (copyright) to manufacturers and other customers, for multiplication, for sale by such manufacturers, or private distribution by customers.

9. If the reproduction were the customer's own likeness.

10. And if something else, e.g. (a) a statue, (b) oil or water-colour painting, (c) a magic-lantern slide, from pictures in illustrated magazines, paintings, etc.

11. Where such magic-lantern slide is projected on the screen and exhibited

(1) To the public for profit.

(2) To private spectators for amusement by an amateur, or lecturer, or expert in science and art.

It is certainly (8) an infringement to make negative copies of copyright photographs. Equally, the issue of prints from negatives so made would be an infringement. Both parties would be separately liable to action.

The fact of the photograph being the customer's own likeness (9) need not affect the matter, unless he had paid for the sitting the usual course—that is to say, unless the copyright was his.

Negatives or other reproductions may only be made of any object when (1) the person giving the order is the owner of the copyright, is acting for the owner, or (2) when there is no copyright in the object copied. (Answer to 10.)

If the form of the copy be a magic-lantern slide (11), the act is

one of infringement, and it is also infringement to exhibit the copies (1) to the public for profit, and (2) privately. The Copyright Act does not distinguish between different kinds of exhibition.

12. A paints or gets painted a background for photographic use from a copyright design or photograph supplied by B, his customer.

A. For use in his own studio (a) generally, (b) for photographing B to his order therewith, (c) for a present to another photographer

B. For sale.

The use (12) of a photograph (in which there is copyright) in the form of a background will certainly be infringement for whatever purpose the background is made. Both the copying and the exhibition, or display, of the background will constitute infringement.

13. In cases 1 to 12 if A is a foreigner and the reproduction is made in a foreign territory for foreign use.

Legally, copyright in an artistic work is unsustainable in a foreign country only when one of the countries does not subscribe to the Berne Convention of International Copyright. Most civilised countries are, however, subscribers to the Convention; the principal exception is the United States of America. Thus (13) if A in Italy copies a photograph in which there is copyright in Great Britain, A exposes himself to action for infringement.

14. If the foreign reproduction is supplied to order of a British subject in British territory.

The liability referred to under (13) is not affected by the nationality of the parties to a transaction.

## THE INFLUENCE OF THE PROPORTION OF BICHROMATE ON THE SENSITIVENESS OF ENAMELENE SOLUTIONS.

(A communication to "Photographische Korrespondenz.")

Eder's "Year-Book" for 1907, page 169, I published some details to the influence of various substances on the enameline solution employed in printing half-tone plates for etching. The following experiments have been made in further investigation of this subject, and are confined to the effect of varying proportions of bichromate the sensitiveness of the coated plates. In these experiments which have been made in the Imperial School of Graphic Arts, Vienna, I prepared a number of enameline solutions, all of which contained the same proportion of Le Page's fish glue, water, and albumen, and differed only in the proportion of bichromate. This latter is given per cents. of the mixture of fish glue and solid albumen; that is say, an enameline solution of 30 per cent. bichromate has the following formula:—

Fish glue .....	30 ccs.
Water .....	70 ccs.
Ammonium bichromate (1 in 10 solution).....	10 ccs.
Albumen solution (1 in 5) .....	20 ccs.

The plates were prepared with the different solutions, printed for the same length of time under a negative, each series of experiments including a short, normal, and a full exposure. These experiments gave the following results:—In the case of exposures by diffused daylight or sunlight a film containing about 10½ per cent. of bichromate proved the most sensitive. The formula is:—

Fish glue .....	20 ccs.
Water .....	45 ccs.
Ammonium bichromate solution (1 in 10) .....	35 ccs.
Albumen solution (1 in 5) .....	20 ccs.

Solutions containing from 9 to 12 per cent. bichromate gave results very little different from the above, whilst the films with less bichromate separated from the plate on development. Others with more bichromate (15 to 20 per cent) swelled up strongly after development and separated to some extent from the plate. Moreover, in the case of the stronger solutions the half-tone dots printed more strongly on the surface of the film.

When printing with mercury-vapour light (Cooper-Hewitt system), a film containing 6 per cent. bichromate proved the most sensitive, those with 4 per cent. adhered badly to the plate in development, while those with 9 per cent. swelled very slightly. The same result

was obtained on exposing with the "Dauerbrand" lamp. Here, again, a strength of 6 per cent. proved the best.

The fact that strongly bichromated films require longer exposure than those less strongly bichromated is to be attributed to a kind of screen action in the film. In order to decide this point I prepared two solutions, to one of which (a) I added about 9 per cent. bichromate, and to the other (b) about 24 per cent. In the case of the above experiments the 9 per cent. films were very sensitive, whilst the 24 per cent. proved very insensitive and adhered badly in development. In the latter experiment, solution (b) was strongly diluted in order to give a thinner film which could be printed through and would not therefore give the same screening action as a thicker film. The two formulæ run as follows:—

(A) Fish glue .....	30 ccs.
Water .....	50 ccs.
Ammonium bichromate solution (1 in 10).....	30 ccs.
Albumen solution (1 in 5) .....	20 ccs.
(B) Fish glue .....	30 ccs.
Water .....	40 ccs.
Ammonium bichromate solution (1 in 10).....	80 ccs.
Albumen solution (1 in 5) .....	20 ccs.

The zinc plates prepared in this way were printed in daylight under the same negative for the same length of time. It was seen that the strongly bichromated but thinner film (b) was just as sensitive as the weakly bichromated thick film (a).

The resistant properties of the enamel were also the subject of observation. The dry plates were burnt-in for the same time and etched in aqueous 5 per cent. nitric acid. The thinner enameline of the film (b) withstood somewhat longer etching than the thicker enameline of solution (a). It was thus seen that the proportion of bichromate is of great influence on the hardness of the enamel, and therefore explains the favourable action of the tanning mixture of chrome alum and bichromate on fish glue prints.\*

The addition of chromic acid or about 1 cc. of ammonia to the first experimental solution above mentioned produced both by daylight and mercury-vapour a depreciation of the maximum sensitive

\* Compare Tschörner, "Phot. Korr.," 1901, page 679.

ness, as regards the proportion of bichromate, the results were the same as without this addition. Experiments have thus shown that for printing by daylight a proportion of bichromate about 10 per cent. gives the greatest sensitiveness in the case of films of normal thickness, whilst in the case of the Dauerbrand lamp, a proportion of 6 per cent. is the best. Thicker films require for the production of the same sensitiveness as the normal mentioned above a lesser proportion of bichromate, whilst thinner films under the same conditions can do with a relatively stronger proportion of bichromate. The fully bichromated film giving a hard enamel, it is advantageous to add to the enamelling solution slightly more bichromate than is necessary for obtaining the greatest sensitiveness. The average formula which can be recommended is as follows:—

Fish glue .....	30 ccs.
Water .....	40 ccs.
Ammonium bichromate solution (1 in 10) .....	40 ccs.
Albumen solution (1 in 5) .....	20 ccs.

J. TSCHÖRNER.

#### THE PROFESSOR OF PHOTOGRAPHY AT DRESDEN.

DR. R. LUTHER, whose appointment to the Professorship of Photography in the newly founded faculty of photography in the Imperial Technical High School at Dresden we announced in our last issue, is the subject of a notice in our Dresden contemporary, "Die Photographische Industrie." Dr. Luther was born in Moscow in 1868, and after passing through the universities of Dorpat and Leipzig became assistant to Professor Beilstein in 1890-1894. From 1894-1896 he was assistant to Professor Ostwald in Leipzig, and in the latter

year became assistant in the Physico-Chemical Institute of the Leipzig University, from which position he was promoted to that of sub-director in 1900. Since 1906 he has been Extraordinary Professor for Physical Chemistry at Leipzig. During his university career Dr. Luther has contributed many papers on photo-chemistry, notably those on reversible photographic processes, the latent image, the swelling of gelatine, the oxidation of sodium sulphite and of sodium thiosulphite in the air.

The photograph which we reproduce is from the well-known studio of Perscheid, Leipzig.

HERR HANS SCHMIDT, the author of several popular handbooks on photography in Germany, has been awarded by the Vienna Photographic Society the Society's silver medal on account of his published works.

#### RAPID PHOTOGRAPHY.

Writing in our Philadelphia contemporary, the "Bulletin of Photography," "Professional" says:—Occasionally we see advertisements offering some wonderful method for sale, but those reading the following simple descriptions will be in a position to turn out just as good work, either as proofs or finished work (where no retouching is required), as can be done in any other way, and without any special apparatus of any kind.

My method of work is as follows:—The plate is exposed in the usual way, then developed with metol-hydroquinone in an Ingenio tank, the plate then being transferred to a fairly strong hypo bath, to which a little formalin has been added to harden the film. By this means the negative is ready to print from in five minutes after exposure.

After taking the negative from the fixing bath, it is rinsed in water and then put between blotters, where the surplus water is blotted off by passing an ordinary mounting roller over it. (The formalin in the fixing bath hardens the film so that it will not stick to the blotters.) The back is then wiped with a soft rag and the negative placed in the printing-frame.

It is better to use a larger printing-frame than the size of the negative, having a piece of plain glass in it and a piece of card cut out to the size of the negative. This prevents the negative from slipping about, and any shaped mask can be used between the card and the glass. When the negative is in the frame and a suitable mask adjusted, a thin piece of celluloid is laid on it and the air-bells expelled by rubbing down with a rag.

Now we are ready to print, and the paper or postcard is placed in position, exposed, developed, and fixed in the usual way, and the finished picture can be in the final washing water in fifteen minutes after the exposure. If thin, clear celluloid is obtained, no blur will show on the finished print, and I have photographs that are just as sharp and clear as it is possible to get from a dry negative. After a sufficient number of prints have been taken from the negative, it should be put in water, washed, and dried in the usual way.

The whole secret is in placing the celluloid between the negative and the paper, and although this is known to a good many people there are thousands who have not heard of it, and who wonder how postcards are turned out so quickly.

## Photo-Mechanical Notes.

#### Electrolytic Etching of Printing Plates.

A method has recently been patented (Specification No. 23,319, 1906), in which the printed metal plate, bearing a resist of bichromated albumen or fish-glue, is employed as the anode in a concentrated solution of a tanning agent. The cathode is composed of metal similar to that of the printing plate. The patentee, Dr. Hans Strecker-Aufermann, of 2, Friedrichstrasse, Munich, claims to have discovered that the hardened layer of bichromated fish-glue upon the metal plate permits an electric current to pass; upon this he bases the electrolytic process. The electric current permits of copper, which is provided only with a coating of chromated glue, being etched not only with iron chloride, but also with other salts, such as zinc chloride, which in a purely chemical application do not etch copper at all. As an electrolyte any concentrated solution may be used which has a tanning action on the layer of bichromated glue. The solution of ferric chloride usually employed is convenient; but any of the solutions which are employed as tanning agents for glues, etc., can be employed with the same good results. Such are sulphate of ammonium, sulphate of zinc, chloride of zinc, sulphate of magnesia, hypo, sulphate of copper, chloride of copper, sulphate of nickel, sal ammoniac, chloride of sodium, sulphate of sodium, chrome alum, ferricyanide of potassium, chloride of manganese, ferrous chloride, chloride of chromium, and so on, in aqueous solutions. The plate is protected at its edges against the etching action by a coating of varnish, and is suspended in the bath as anode. The material of the cathode may be of any kind. The electrolyte is an aqueous solution of one of the foregoing tanning agents. After about five to fifteen minutes the layer composed of glue or the like swells to different thicknesses according to the image. The

quit, having been interrupted up to this point, is now closed and etching begins, the ion of the acid passing to the metal through the layer, which acts as a diaphragm, whilst dissolved metal goes to the cathode. As the current varies according to the thickness of the layer, which in turn is dependent on the greater or less exposure of the film, an etching is obtained corresponding to the image. The process can very advantageously be carried out by arranging a desired number of etching plates, the faces whereof are all directed towards the cathode, and are consequently anodic, whilst the backs, which remain bare and must not be varnished, are all directed towards the anode, and are consequently cathodic. All the anodic sides are etched, whilst the dissolved metal precipitates on the cathodic sides, or hydrogen is set free on them when certain electrolytes are used. The intensity of current must be kept within narrow limits—i.e., between 0.35 and 2 amperes per square centimetre. The electrolyte is generally ferric chloride at 42deg. to 48deg. Baumé. The concentration of the bath is high. It is, however, sometimes necessary to use baths which gradually become weaker, or to produce a dilution of the bath by introducing water. The dilution can also be produced by separating the anode chamber from the cathode chamber by means of a diaphragm and using a diluted solution in the cathode chamber, whilst the anode chamber contains a concentrated one. Diffusion causes the degrees of concentration to equalise—i.e., the solution in the anode chamber becomes gradually weaker. Thus it is not possible to give a fixed current; it is, on the contrary, necessary to follow other well-known indications. When the etching operation is completed the plate is cleaned with caustic soda, after which it is re-etched in the ordinary or in the above described manner. It is not necessary in the above process to supply current from an external source. It is, for instance, possible, as in the well-known Daniel cell, to provide a zinc plate, carrying a layer of bichromated glue or a similar material and a copy of the image, and to dip it into sulphate or chloride of zinc or ferric chloride in front of a copper or lead plate arranged in a porous cup containing a suitable depolarising fluid, so as to obtain a cell having zinc and copper as poles and a diaphragm. In order to prevent (in this case as well as in the process wherein an outside current is made use of) any precipitation of hydroxide of iron which, when zinc etching is carried out, would be formed behind the layer, a suitable material, such as ferricyanide of potassium, oxalic acid, sugar, glycerine, citric acid, tartaric acid, acetate of soda, etc., is preferably added to the ferric chloride. When the circuit of the cell is closed on a resistance or when the cell is put into short circuit, the etching process takes place. Similarly, a Leclanché cell can be formed with sal ammoniac or sulphate of ammonium as an electrolyte, and a solid depolarising agent, for instance, peroxide of manganese, the circuit of this cell being closed on a resistance or short-circuited.

## Exhibitions.

### SOUTH LONDON PHOTOGRAPHIC SOCIETY.

In obtaining the use of the South London Art Gallery, Peckham Road, the South London Photographic Society is to be congratulated on the new opportunities for more adequately displaying their exhibition, opportunities which, it must be admitted, they have used to very great advantage. The collection of photographs to be exhibited until March 21 must be considerably less in number than those we have visited for the past few years at the Camberwell Baths, but the show is none the worse for that, and surprisingly better than the very excellent hanging it has received. In their old quarters the Society were forced to do the work of hanging within very small limits of time, but with the accession of more convenient accommodation they have demonstrated their ability to do justice to the work submitted to them. As in previous years the members' classes, and particularly that set aside for architecture, are a strong attraction of the show. The bronze plaque in Class A goes to Dr. Evershed for "La Brunette"; No. 14, a piece of work which we confess we like less than Dr. Evershed's usually attractive excursions

amid London scenes, on the ground that it lacks variety of tones in the face, and gives an unpleasant suggestion of illness to the subject. Miss M. A. Smart receives a bronze plaque for No. 36, "Apple Blossom," a quite excellent piece of photography of such subjects, and mounted very appropriately.

In Class B the bronze plaque goes to Mr. E. Pady for No. 62, "Christchurch," which has good qualities of light and airiness. No. 67, "Beyond," by G. J. T. Walford, is a subject of the opposite class, but well treated and full of the rich tones and shadows which belong to a dark subject of this kind. Mr. Gideon Clark, the secretary of the South London Society, is commended for No. 76, "A Refuge and Strength," a rendering of a church which caps a hill and dominates the town collected in the valley below. It is a piece of composition which is not without certain sentiment, and well carries out its title. In Class C the bronze plaque goes to Mr. Clark for No. 103, "Chingford Marshes," a very good rendering of a marsh stream; it receives the gold medal awarded to the best picture in the exhibition. Mr. Clark shows his work in almost every class, and is certainly to be congratulated on the high pictorial standard which he maintains. His "Three to Form a Quorum," No. 159, in Class D, is a clever piece of figure study in sunshine, which, however, does not receive an award. "Gossips," No. 171, by H. Creighton Beckett, is spoilt by the line of light which crosses the centre of the picture and gives to the side of the tunnel which forms the foreground almost the effect of a dark mount. In Class F, Dr. Evershed receives a silver plaque for "Lingering Mist," No. 187, though we must confess to feeling dissatisfied with the print as a rendering of this aspect of nature. The veil which masks the more distant portions of the subject seems to rise from one point, and suggests a bonfire more than a mist. Dr. Evershed's "The Signal Box," No. 180, is, we think, immensely better as regards composition, and is technically a better oil print than the medalled picture. The open classes supply a good deal of excellent work, and include perhaps half a dozen or a dozen subjects which might very well have been dispensed with. Mr. G. R. Henderson in "Lilith," No. 193, should use a moulding one-quarter the thickness, and he would then get the advantage of the really dainty mounting of the print. "A Reverie," by Mr. and Mrs. Bracewell, No. 211, is an altogether dainty piece of work. No. 220, a multi-colour print by Edward Warner, obtains a good deal more success than is usual in experiments of this kind. Miss Agnes B. Warburg's "Spring," No. 251, is as commendable a piece of work as any in this class, though it has not attracted the judge's favour, the awards going to "Low Tide," by Walter Selfie, No. 316; "The Garden of Allah," by Louis J. Steele, No. 302; to Basil Schon for "Dingy London," No. 273; to E. R. Bull for "Light and Shadow," No. 246; and to G. J. T. Walford for "Norwich Cathedral," No. 234. There is a section devoted to colour-photography, in which Mr. Henry J. Comley receives a bronze plaque. The exhibition also includes an invitation section as well as a number of trade exhibits, including those of Messrs. O. Sichel and Co., R. and J. Beck, Ltd., Ross, Ltd., Spiers and Pond, Walter Tyler, the Alstona Gallery, and "The Amateur Photographer." Owing to the death of Mr. Horsley Hinton and the indisposition of Mr. Furley Lewis, by whom, in conjunction, the exhibition was to have been judged, the awards were made by Mr. F. J. Mortimer; those in the colour-photography and technical section being made by Mr. E. J. Wall. A word should be said for the excellent production and printing of the catalogue, the work of the St. Clement's Press.

**STREATHAM EXHIBITION.**—The members of the Streatham Portfolio held their second annual exhibition on February 27, 28, and 29, which was very well attended, admission, catalogues, and refreshments being free. The pictures were hung on artistic canvas screens, with natural hanging surface and dado of chocolate distemper finished off with stained wood skirting and rails. The pictures showed distinct evidence of an all-round advance since the last exhibition, which suggests that societies run on the lines of the Streatham, with every effort being directed to advancement through the portfolios, and with meetings of a secondary and social nature, are likely to be very useful in producing better work. Particulars of membership can be obtained of the hon. sec., Mr. F. E. Huson, 56, Salford Road, Streatham Hill, S.W.

## FORTHCOMING EXHIBITIONS.

- March 7 to 14.—Leicester and Leicestershire Photographic Society. Sec., Lewis Ough, F.C.S., Fernleigh, St. James's Road, Leicester.
- March 7 to 21.—South London Photographic Society. Sec., E. Pady, 260, Southampton Street, Camberwell, S.E.
- March 12 to 14.—Shropshire Camera Club. Sec., W. D. Haydon, The Schools, Shrewsbury.
- March 14 to 21.—Sunderland Photographic Association. Sec., W. E. Kieffer, Stirling Street, Sunderland.
- March 16 to 19.—Cripplegate Photographic Society. Sec., J. G. Denyer, 15, Ostade Road, Brixton Hill, S.W.
- March 18 to 21.—Nottingham Camera Club. Sec., S. W. B. Vines, 101, Sherwood Street, Nottingham.
- March 21 to 28.—Midlothian Photographic Association. Entries close March 14. Sec., Robert Oliver, 6, Marieston Terrace, Edinburgh.
- March 30 to April 4.—Malvern Camera Club. Entries close March 21. Sec., J. B. Nickolls, The Exchange, Malvern.
- March 31 to April 4.—Sheffield Photographic Society. Hon. Sec., J. W. Wright, 62, Vale Road, Sheffield.
- April 21 to 24.—Southend-on-Sea Photographic Society. Entries close April 6. Sec., J. Archer, 24, Ashburnham Road, Southend-on-Sea.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were received between February 24 and 29:—

**PACKING PLATES.**—No. 4,153. Improved packing for photographic plates or films. Marian Romanowicz, 322, High Holborn, London.

**PRINTING.**—No. 4,190. Improvement relating to photographic and postcard printing machine and the like. Ellis Graber, 16, Newton Road, Tunbridge Wells.

**PACKING PLATES.**—No. 4,338. New or improved method of and means for packing photographic plates, films, and the like. Guy Arthur Chambers, 55, Chancery Lane, London.

**PHOTOPHONE.**—No. 4,391. Electric photophone for the production of photophonographs or use as a telephone transmitter, also means of reproducing sound from photographs thus obtained. Josiah Frederick Child, 258, Rosendale Road, Herne Hill, London.

**"ELECTRIC ARC" PRINTING.**—No. 4,394. Revolving table made to carry any size printing frame for printing with the "electric arc." Edgar Watson Bowes, 16, Ethelden Road, Shepherd's Bush, London.

## New Trade Names.

**MOTOGEN.**—No. 298,091. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives, but not including photographic developers, and not including any goods of a like kind to photographic developers. Allgemeine Petroleum-Industrie-Aktien-Gesellschaft, Unter-den-Linden, 35, Berlin, S.W., 64, Germany, manufacturers. November 18, 1907.

**ALBUMAT.**—No. 297,799. Photographic paper. Vereinigte Fabriken Photographischer Papiere, Blumenstrasse, 80, Dresden, A., Germany, manufacturers. November 7, 1907.

**CARBONIVRO.**—No. 299,160. Photographs. George Davison Reid, 151, Barras Bridge, Newcastle-upon-Tyne, photographer. December 30, 1907.

**A DAMAGED SHOWCASE.**—One night last week some person or persons are alleged to have wilfully upset a valuable photographic showcase erected in front of Mr. Jerome's premises, 283, Lord Street, Southport. The case was valued at about £25, and was well built, the covering being of lead. The police have the matter in hand, and have issued notices of a reward of £5 for such information as will lead to a detection and conviction.

## Analecia.

*Extracts from our English weekly and monthly contemporaries.*

## An Improved System of Mounting.

THAT a mounted photograph should lie flat and without curl or cockle (writes Mr. Nelson K. Cherrill in "The Photographic Monthly") is an absolute desideratum. Nothing is more destructive of pictorial illusion than unevenness of surface; so much so that the most distressing fate which can befall a really fine print is to get pasted into an album, where, in the general run of things, it will ruin itself and disfigure the book by giving a persistent warp or curl to the page on which it is stuck. Every kind of mountant in ordinary use is prepared with an aqueous solvent, the moisture from which is the cause of all the difficulty of flat mounting, as no means have yet been discovered of exactly balancing the expansion and contraction of the picture and its mount. A vast amount of ingenuity has been expended in the endeavour to overcome this apparently simple trouble. Probably the best solution of the difficulty up to the present time is that offered by the "Dry-Mounting Process," in which a dry print is forced into close contact with a dry mount in a heater-press. To the ordinary amateur, however, this system has two drawbacks: it requires a somewhat costly outfit, and it does not seem applicable to mounting pictures in a book. The process I am about to describe is carried out with a non-aqueous solvent, so that it has no tendency to cockle even the thinnest mount. It requires no heat and only a moderate pressure, so that it is equally applicable to mounting in a book or on separate sheets. The manipulation is also exceedingly simple. It is as follows:—Coat the back of the dry (and preferably untrimmed) print with shellac varnish, which is merely a solution of shellac in methylated spirits. When the varnish is dry the print may be mounted at once or at any future time. To mount it, all that is necessary is to rub over the surface to which it is to adhere with a small quantity of a mixture of acetone and alcohol, and to apply the print at once with a firm pressure which extends all over the surface. In two minutes the solvents will be dissipated and the mounting complete. Anything of its kind more simple or easy of execution it is difficult to imagine.

## Control of Contrast in Carbograph Printing.

In an article dealing with the above subject in the current issue of "Photo Notes" the writer states that contrast can be lowered by selecting a light tone pigment. Considering the brown tones available in carbograph, and ignoring the effect of after reduction, we have two light-toned browns in cold and warm sepia. Either of these gives a soft image from a negative of ordinary pluck and density, though the same negative may give hard results with blocked up shadows if we use "photo brown," "engraving black," or "red chalk." It should be noted that the "engraving black" is not a pure black—such a colour is hardly necessary in a carbograph process—it is a very deep brownish black which may perhaps best be described as an extremely dark sepia. The "red chalk" is also a brown of a very red tint if the silver is not removed by Farmer's reducer. If, however, our negative is very thin and soft we can gain pluck and contrast in the enlargement by using one of the three papers last mentioned, "engraving black" being perhaps best suited to the thinnest negative, while of the other two "photo brown" gives the strongest result.

**YORKSHIRE PHOTOGRAPHIC UNION.**—The annual meeting and exhibition of prints will be held in the Municipal Institute, North Street, Keighley, on Saturday, April 4.

**L.C.C. PHOTOGRAPHIC APPOINTMENT.**—As an experiment for one year the photographic work of the London County Council is to be done in the chemical and gas testing department by one assistant, at a salary of £200 a year, and two assistants and a boy at the rate of pay not exceeding 40s. and 15s. a week respectively. Thirty-five applications have been received for the first-mentioned post, and the Establishment Committee has, subject to the usual sanction, and to the candidate passing a medical examination satisfactorily, appointed Mr. Arthur Edward Lane. He is to give his whole time, and must not undertake any other work.

## New Books.

**Agenda Lumière.** 1908. Paris: Gauthier-Villars. Lyons: A. Lumière et ses Fils. Fr. 1.

Year by year MM. Lumière and their talented collaborators publish the results of experiments made in the Lyons laboratories. Since the results are usually of practical and permanent value we are glad to find the full texts of the papers collected in the year-book of formulæ and directions which the house of Lumière have issued for some years past. Moreover, the Agenda also gives a complete list of the photographic communications from the Lumière laboratory since the first, in 1892. The Autochrome plate, as we should expect, receives due attention, and the full directions for its use occupy pp. 62 to 79. Numerous tables of weights and measures, exposures, and optical matters constitute the middle portions of the book, whilst the later pages are devoted to a formulary for the photographic processes, the directions for the use of the Lumière chemical products, and to a record of exposures, in conjunction with which latter a series of perforated gummed labels is presented, enabling the entry in the register of exposure to be instantly turned out. Although issued in French—at the absurdly low figure of one franc—the book contains much of value to interest the English. Doubtless copies can be obtained through the English house of Lumière and Co., at 79, Great Russell Street, London, W.C.

**MINIATURE PRINTING.**—The "Photo-Miniature," we are glad to see, appearing with its once wonted regularity. The current issue, No. 86, reaches our table this week, and is found to be a manual of the carbon process, the modern methods of which receive careful consideration. Thus we find some words of appreciation of the Kodak Company's spirit sensitiser, notes on Mr. H. W. Bennett's latest sensitising formula, directions for the transfer of the carbon image to various final supports, in addition to brief descriptions of the latest developments in pigment printing, ozobrome, and carbochrome. The "Miniature" is issued in this country by Messrs. Swan and Ward at 6d. nett.

## New Apparatus, &c.

**Shape Holder.** Made by Kodak, Ltd., 57 to 61, Clerkenwell Road, London, E.C.

A very useful and inexpensive accessory for the professional photographer is provided in this little piece of apparatus, which is designed

to assist in the cutting of oval or circular prints, and is certainly an effective aid in such work. It consists of a board provided with a spring similar to that of a printing frame. The spring serves to

hold the print under one end of the cutting shape so that pressure of the hand at the other firmly secures it and leaves the worker's other hand at liberty for making the cut. The apparatus is of a size suitable for using up old whole-plate negatives as the cutting base. The price of the apparatus is 1s. 6d.

**The "GGE" Tripod Bolt.** Made by Gustav Geiger, 16, Maximilian Platz, Munich, Germany.

This piece of apparatus is a substitute for the tripod screw, and should be particularly useful for hand-cameras, the use of which on a tripod would be practised much more (with advantage to the results) were it not for the time wasted in attaching the camera to the tripod head and removing it therefrom. In the "GGE" there is no screw, but, instead, the vertical pin of the apparatus is pushed into the socket

of the bush and firmly locked there by the horizontal bolt shown in the figure. The construction permits of the camera being turned on its head just as can be done with a relaxed screw attachment, whilst the certainty and speed of the action certainly commend the accessory to the notice of hand-camera workers. The price of the bolt is 5 marks (5s.).

**The Diamond Oval and Circle Cutting Machine.** Sold by Kodak, Ltd., 57 to 61, Clerkenwell Road, London, E.C.

This new piece of apparatus provides for the rapid cutting of oval prints and oval cut-outs, possesses a wider range of adjustment, and is more substantially built than any instrument of the kind which we have yet seen. The machine will cut a circle up to 22in. in diameter, and an oval up to 22in. by 32in., either dimension being instantly obtained by setting each of the two scales. The angle of the cutting knife can also be adjusted to give a bevel outwards or inwards, or to cut perpendicularly as usual in trimming prints. Moreover, a diamond can be used in place of the cutting knife and glass or opal cut in the same way. The machine having been adjusted to a given size, any number of cuts can be done with great rapidity; in fact, the setting itself for a given oval or circle is a matter of a few seconds only. The machine should certainly be a valuable acquisition to the establishment of a photographer who prefers to make his

mounts suit the subject rather than rely invariably upon the stock mounts which he can purchase. The price of the apparatus, complete with knives and base, is £5.

The No. 3 B Carbine Folding Camera. Sold by W. Butcher and Sons, Camera House, Farringdon Avenue, London, E.C.

In this new model of folding film camera a quite new feature is the front which moves forward, and is locked in any position in a most rigid manner. The camera provides for the exposure of both plates

and films, and has focussing scales for both. Its other fittings comprise "Automat" shutter, rising and cross fronts, reversible finder and level, and Beck symmetrical lens. It is altogether a substantial instrument, and handsome in appearance. In quarter-plate size the price is £3 3s., in postcard £4 4s.

The Patent Newton Finder. Made by Gustav Geiger, 16, Maximilian Platz, Munich.

From a specimen of the finder submitted to us we see that one very good point in its favour is the automatic opening. On touching the lever on the right both the lens and the sighting-rod of the

finder fly up and fix themselves at right angles to the base. Similarly, on pushing down the lens, the sighting rod automatically "ducks under" the latter, and is thus protected from damage. The finder gives a picture 1 1/4 in. x 3/4 in., and costs, retail, 4s. 6d.

THE MOUNTANT SQUEEGEE.—Messrs. Houghtons Ltd. have issued a novel outfit which should appeal strongly to amateur workers for the reason that it means economy and absence of mess in the mounting of prints. It consists of a small spatula (with which a little of the usual semi-solid mountant is applied to the back of the print) and of a rubber squeegee of special form. This latter is used to spread the mountant evenly over the print, for which purpose it has the advantages of absorbing no paste and depositing no hairs. Both spatula and squeegee can be made perfectly clean in a moment or two, and the outfit, which costs only 6d., therefore prevents accidental contamination of the mountant in the most effective manner.

BENZOLE, BENZINE, BENZOLINE, AND BENZENE.—A correspondent of the "Chemist and Druggist" usefully calls attention to the confusion which exists between these various names. As he states, petroleum spirit is often marked and rightly so, "benzine." "Benzoline" refers to the same article, a light grade of paraffin. Benzene (= benzo<sup>le</sup>), on the other hand, is a coal-tar product, and is known in scientific books as "benzene," but more popularly as "benzole." As pointed out by the correspondent of our contemporary, petroleum spirit answers well for cleaning purposes, whereas benzole is necessary as a solvent of rubber.

## New Materials, &c.

"Deleto," tinting medium for negatives. Made by The Aerograph Co., Ltd., 43, Holborn Viaduct, London, E.C.

This new preparation is brought out by The Aerograph Co. specially for aerograph work, where it is required to lay graduated tints on negatives or form vignettes. It may be used for lightening masses of shadow in which use can be made of a mask or stencil cut from a print from the negative, and used as a shield to confine the action of the medium. The employment of a mask is a very common practice in aerograph work on a large scale, and the firm's suggestion of its application in such work as the above will no doubt be found of considerable service. An advantage of the preparation is that it takes to the glass as well as to the film side of the negative. After some considerable use of Deleto, we have no hesitation in saying that those using an aerograph will find it a most useful preparation for working on a negative. We find that it adheres well to the glass side of the negative, making it quite easy to soften masses of shadow without the suggestion of an outline. Its facility of application to both sides of the negative enabled us to produce very pleasing effects. For artistic vignetting, especially in the case of heads, it should certainly be an invaluable material. "Deleto," it should be added, does not mix with water, and the aerograph should therefore be given a wash-out with spirit before using it. For the same reason it is best not to allow the medium to dry into the air-brush, but if this takes place, a little benzole will speedily remove it. The material is put up in bottles at 1s. 3d. and 2s. each.

Tabloid Sepia Toner (Improved formula). Made by Burroughs, Wellcome and Co., Snow Hill Buildings, London, E.C.

Since we reviewed the "tabloid" set of ferricyanide-bromide and sodium sulphide, the latter compound has been replaced by a thio-stannate, in accordance with Messrs. Burroughs Wellcome's recent patent. In fact, we are informed that for some time past, the sulphiding compound on the market has been thiostannate, a fact referred to by Mr. Welborne Piper in his articles of a couple of weeks ago. In several respects the change is for the better. The "toning" solution is much less odorous, though it is not—and Messrs. Burroughs Wellcome do not claim that it is—completely without odour. It is more stable and it is less liable to decomposition than is sodium sulphide. The makers have found that the occurrence of yellow-brown colour is due to the formation of traces of hypo in the sulphide, a tendency which the thiostannate does not exhibit. The constituents for both baths are put up in the convenient "tabloid" form, and the set, like all other chemicals of Messrs. Burroughs Wellcome, is issued with full directions for use.

ANTIQUE SELTONA.—A new variety of Seltona, the well-known self-toning paper of the Leto Photo-Materials Co., Ltd., has been issued under the name of "Antique." "Antique Seltona" proves in our hands to possess a most pleasing surface, a very fine semi-matte, and to tone with the ease which we have learnt to expect in the glossy, matt, and other varieties of the papers. The makers, we may add, have just issued a booklet of instruction in appreciation of Seltona papers. A supply of this publication, which is essentially for distribution by dealers, is obtainable on application to 3, Rangoon Street, London, E.C.

CARBGRAPH ENLARGEMENTS.—The Rotary Co. has issued a circular of prices at which they are prepared to undertake "Carbograph" enlargements by their new process of that title. There being no enlarged negative required, the prices are fixed on a moderate scale for such work—4s. for a 12 x 10 enlargement. Working-up and finishing in monochrome and colours can be done at the usual prices already in force with the Rotary Co. A carbograph enlargement, whether of pure pigment image, or backed with that of the "bromide" image, may be considered fully as permanent as a print done of carbon tissue in the ordinary way.

SPRING PRINTING.—In the spring the photographer's fancy lightly turns to thoughts of—drawing sitters into his studio! Tennyson up-to-date! It is doubtful whether the tractive force is always employed in the best way, and therefore we are glad to draw attention to a new leaflet issued by Messrs. Walter Pearce and Co.,

entford, under the title, "Portraits, Enlargements, and Miniatures the Spring-time." Messrs. Pearce have a way with them as pters, and the little special circular, only 6in. x 3in., done in en and white, is daintily inspiring, with never a suggestion ut it that its real object is to draw customers to the photo- upers. The brief letter-press is in accord with the get-up, and y two combined make it a most recommendable piece of stationery a kind which a photographer could not possibly obtain from his al printer. Choice paper, decorative type, and perfect inking rarely found except in the productions of specialising firms such Messrs. Pearce, who, of course, limit the issue of the folder one photographer in a town and offer to insert the special par- tials as regards prices—all at most moderate charges. Those who sho to make effective use of postal advices to their customers not conceivably do so in better shape than by means of the new der.

**'CARFOLIO' FOLDER PORTRAITS.**—The ability to show his public distinctive style of portrait being a photographer's most valuable upon, it is to the credit of Messrs. Raines and Co. (of the Raines) Service no less than of Ealing, Middlesex) to have pre- pared a form of portrait print which can be shown by a photo- grapher and is pretty certain of attracting notice and receiving proba- tion. The "Carfolio," as it is termed, is a folder portrait, rich has outstanding merits in the way of attractive appearance d cannot possibly be charged with looking cheap. The paper of a folder itself, the colour and texture of the print, the filigrane vering tissue—all, down to the mauve ribbon, are true to the neral scheme, and, placed in a photographer's window or show- se, are bound to impress customers as being something in the ture of a "creation," and therefore deserving of the enhanced price ich, for example, the *dernier cri* in Paris hats secures in com- ison with feminine decoration of humbler origin. In short, ssrs. Raines have a good special line in the "Carfolio," sell it a moderate price, and use their discretion in its dissemination.

## CATALOGUES AND TRADE NOTICES.

**HOUGHTONS' 1908 CAMERAS.**—The new large list just issued by ough- tons Limited measures 11in. by 8½in., and permits of the prop- riate display of the many types of cameras actually manu- tured by the Holborn firm. These include box cameras of all tterns and prices, reflex and folding cameras, the minute (to be operly accented) "Ticka," film cameras, box and folding, noramic cameras, tourist cameras of all degrees, and, lastly, the significant "Sanderson" in its various forms. Messrs. Houghtons n justly say that this list (which is sent free) gives the intending rchaser an excellent idea of how to lay out his money to the best vantage.

**W. WATSON AND SONS** have just issued a list of second-hand meras and lenses, all of which they guarantee to be in good ndition. The makers' names attached to the apparatus are suffi- ent guarantee as to the quality of the original workmanship, and om the low prices at which many of the articles are listed it is ry evident that Messrs. Watson are offering some genuine bar- ins. A copy of the list will be sent free on application to the ove firm at 313, High Holborn, London, W.C.

**THE TELLER CAMERA COMPANY**, of 68, High Holborn, London, W.C., nd us a copy of their spring clearance list of second-hand and op-soiled apparatus, etc. The list includes a large selection of nd, stand, and field cameras and lenses by most of the well- own makers, which are offered at prices much below the original st. Tripods, shutters, changing-boxes, roll-holders, and many ccessories too numerous to mention are also included in the list, hich we think will repay a careful study by those about to make ditions to their photographic outfit, or to purchase one for the st time.

**AN EXHIBITION** of the work of Baron de Meyer, and of Mr. A. L. urn, will be opened in the Goupil Gallery, 5, Regent Street Waterloo Place), on Monday next, and will remain open daily from to 6, for about a month.

# Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, MARCH 13.

Cardiff Photographic Society: "Round Towers and High Crosses of Ireland." F. Murphy.  
Bristol and West of England Photographic Society. Rotary Carbohydrate Paper.

MONDAY, MARCH 16.

Caiford and Forest Hill Photographic Society. Lantern Slide Competition Criticism. M. Arbuthnot.  
Scarborough and District Photographic Society. "The Point of View." Dr. J. Harvey.  
Bowes Park and District Photographic Society. "Marine Photography." F. J. Mortimer, F.R.P.S.  
Kidderminster and District Photographic Society. "Bromide Paper Toning." H. W. West.  
Stafford Photographic Society. "Reduction and Intensification of Negatives." Herbert A. E. Hey.  
Southampton Camera Club. The Affiliation Societies' Prize Slides.  
Bradford Photographic Society. "In Search of the Picturesque." W. H. Houghton.  
Cleveland Camera Club. Y.P.U. Slides.  
Walsall Photographic Society. Rotary Carbohydrate Paper.  
Photographic Survey and Record of Surrey. "Survey Work from the Geological and Scientific Standpoint." W. Whitaker, B.A., F.R.S., F.G.S.

TUESDAY, MARCH 17.

Royal Photographic Society. "Architecture in New Guinea." A. H. Dunning.  
Kebley and District Photographic Association. "St. Albans and Lichfield." Godfrey Bingley.  
Epsom and District Literary and Scientific Society. "Lantern Slides." B. J. Edwards & Co.  
Sheffield Photographic Society. "The Land of Carillons, Canals and Coifs." Charles B. Howdill, A.R.I.B.A.  
Wimbledon and District Camera Club. Exhibition of Members' Prints.  
Hackney Photographic Society. R.P.S. Affiliation Prints, 1906.  
Redhill and District Camera Club. "Autochrome Colour Plates." A. Dukinfield Jones.  
Erdington Photographic Society. "Enlarged Negative Making, &c."  
Photographic Survey and Record of Surrey. "Notes on the Folk Lore and Primitive Appliances of Surrey (Superstitions, Obsolete Appliances, House- hold Apparatus, and Children's Games)." Edward Lovett, F.R.H.S.

WEDNESDAY, MARCH 18.

Tunbridge Wells Amateur Photographic Association. "Glimpses of Jamaica." A. Mackie.  
Bristol Photographic Club. "Early Steps in Gum." E. Beaven.  
Woodford Photographic Society. "Autochrome." R. Child Bayley.  
Leeds Camera Club. "My Wanderings with a Hand Camera." A. Nicholson.  
Central Technical College Photographic Society. "The Theory of Time Develop- ment." W. F. Slater, F.R.P.S.  
Croydon Camera Club. "Enlarging and Reducing with Home-made Apparatus." J. M. Sellers.  
South Suburban Photographic Society. "Gun Bichromate." J. C. S. Mummery.  
Borough Polytechnic Photographic Society. Lantern Slide Competition.  
North Middlesex Photographic Society. "Ozobrome." S. C. Puddy.  
Bournville Camera Club. "Enlarged Negative Making, &c."  
Photographic Survey and Record of Surrey. "Ancient Architecture, Ecclesiastical and Domestic, in Surrey." F. M. Johnston, F.R.I.B.A.

THURSDAY, MARCH 19.

South Manchester Photographic Society. "Carbon Printing." H. Holt.  
Optical Society. Presidential Address.  
Rugby Photographic Society. "The Right Way in Photography." Demonstrated with "Tabloid" Photographic Chemicals. R. H. Myers.  
Southend-on-Sea Photographic Society. "The Application of Colour Photography to Book Illustration." H. O. Klein.  
Chelsea and District Photographic Society. Members' Evening.  
Queen's Park Amateur Photographic Association. Annual Business Meeting.  
London and Provincial Photographic Association. "In Search of the Sun." C. P. Butler.  
Blenheim Club. "A Tour in Spain." E. A. T. Wigram.  
Richmond Camera Club. "Time Development." W. F. Slater.  
Hull Photographic Society. "What Can be Done with a Hand Camera." C. P. Goetz.  
Bath Photographic Society. Exposed Plate and Lantern Slide Competition.  
Handsworth Photographic Society. "Handsworth and its Famous Men." E. J. Timing.  
Liverpool Amateur Photographic Association. "The Latest in Ozobrome." Rev. Harry W. Dick.  
Sheffield Friends' Photographic Society. "Enlarged Negative Making, &c."  
Photographic Survey and Record of Surrey. "An Archaeological View of Survey Work." G. C. Druce.

## ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held March 10, the President, Mr. J. C. S. Mummery, in the chair. The Chairman announced the death of Mr. J. Hort Player, an old member of the Society, and inventor of the Player- type process. A gift of books from Mr. G. E. Brown, and one of a new type of selective shutter from Messrs. Dallmeyer, was also announced, and votes of thanks were passed to the donors. Mr. T. Thorne Baker then read a paper on "Phototelegraphy," or the transmission of photographs by wire. After a brief reference to the work of Amstutz, he described in detail the apparatus used by Pro- fessor Korn, illustrating with lantern slides the transmitting, receiv- ing, and compensating apparatus. This was followed by a descrip-

tion similarly illustrated of the transmitter and receiver used by Dr. Belin, and examples of both methods were then shown upon the screen, which examples somewhat surprised the audience, who evidently had not expected to see anything quite so perfect as some of the Belin specimens shown. The slides were supplemented by a bromide print transmitted from Paris just before the commencement of the lecture. An interesting set of slides illustrated the troubles caused by inattentive telephone ladies at the exchanges, who sometimes failed to keep the line isolated, and also defects due to induction. The lecturer, however, took an opportunity of expressing his thanks to the Post Office authorities, who, since the necessity for complete isolation of the line has been recognised, have assisted the experimenters in very possible way. The audience evidently did not feel competent to discuss the matter of phototelegraphy, but in answer to questions by Messrs. McLean, Butler, Dawson, and others, the lecturer explained that while a few prints have been used for newspaper illustration, the generality of the results have not been good enough to permit the process being applied to any particular commercial uses. It had been tried for the purpose of producing a block direct, instead of a simple print, but so far it appeared that the best results were obtained by working from prints. At present a closed circuit was necessary, therefore the telephone wires had alone been used, but probably before long it would be possible to utilise the telegraph cables. The meeting closed with a unanimous vote of thanks to the lecturer.

**EDINBURGH PHOTOGRAPHIC SOCIETY.**—At a meeting of the Edinburgh Photographic Society, on March 4, a lecture on "Recent Developments in Colour Photography" was delivered by Mr. Tudor Cundall, B.Sc., F.I.C., F.C.S. The lecturer reviewed the advances that had taken place in the theory and practice of colour photography since 1900. The processes considered included the Lippman direct method, the Warner-Powrie, and other *additive* three-colour processes, and the Sanger-Shepherd, Pinatype, and other *subtractive* three-colour processes. In criticising the new Lumière Autochrome process, Mr. Cundall said that while he thought it marked a great advance in some ways, it had certain theoretical deficiencies, and that further progress would probably not be along that line. On the whole, he came to the conclusion that, though considerable progress had been made, the three-colour theory needed revision, and that both as regards the making of transparencies, and particularly paper prints, the methods were still lacking in simplicity, rapidity, and exactness.

**SOUTHAMPTON CAMERA CLUB.**—Mr. C. B. Howdill, of Leeds, gave an interesting lecture on Monday last, entitled "Servia and Its People." Mr. Howdill recently made a tour in Servia, and in the form of an illustrated lecture he related some amusing and exciting incidents he experienced. His attentions had been chiefly confined to the study of the manners and customs of the peasantry, and he described several entertaining episodes which occurred in securing his desired photographic records. He explained that the chief occupation of the peasantry was agriculture, which doubtless was the result of free grants of land allotted to them. The average farm dwellings were somewhat primitive in construction, but the Servian possessed surprising ingenuity in accomplishing his employment. The lecture was profusely illustrated with lantern-slides, which portrayed many types of the inhabitants, and also the mountainous and densely wooded nature of the country. Mr. Howdill is to be congratulated on his successful photographic survey he has made of this disturbed and unsettled country, which was not accomplished without some personal risk. A hearty vote of thanks at the close terminated an interesting and enjoyable lecture.

**MR. SPEAIGHT AND THE P.P.A.**—The Professional Photographers' Association has caused the following communication to be sent to Mr. F. W. Speaight, the Senior Managing Director of Speaight, Ltd., the child photographers:—"Dear Sir,—At the last meeting of the committee of this Association, the following resolution was proposed and unanimously carried: 'That the congratulations of the Committee of the Professional Photographers' Association be expressed to Mr. F. W. Speaight upon the successful accomplishment of his Scheme of Improvement at the Marble Arch, now being carried out by the L.C.C.'—Faithfully yours, (Signed) A. MACKIE, Hon. Secretary."

## Commercial & Legal Intelligence

**SOUTHPORT BANKRUPTCY.**—A dividend is to be paid at the Official Receiver's office, Liverpool, on March 18, in the bankrupt estate of James Shaw, photographer, residing and carrying on business at 4, Bridge Street, Southport, Lancs.

**A PICTURE POSTCARD DISPUTE.**—At the Shoreditch County Court on Friday, before Judge Bray, Alfred Henry Cooper, trading as the Photophone Company, at 19, Coleman Street, E.C., sued Sheppard and Company, of 136, Old Street, Shoreditch, claiming £23 6s., the price of goods supplied. Mr. Alexander Neilson, instructed by Messrs. Ward, Berks, and Mackey) represented the plaintiffs. The defendant company's case was conducted by the principal, Mr. Rudolf Shaefer, who made several counter-claims, holding, according to these, that there would be a large balance due to the defendants from the plaintiffs over and above the amount claimed by the Photophone Company, which was in respect of cards printed by the latter for the defendants. It was stated by Mr. Shaefer that the plaintiffs agreed to print for Sheppard and Company 100,000 cards from 100 plates, which the defendants agreed to procure. Part of the cards were to be delivered before Easter, 1907, and the remainder before Whitsuntide. The defendants procured the 100 plates, as they had undertaken to do, but the Photophone Company, in breach of the contract, did not supply any cards whatever before Easter, whereby one of the most important seasons of the year for the wholesale picture postcard trade was lost to the defendants, who, it was alleged, suffered considerable damage as a consequence. The plaintiff company had only printed for the defendants cards from forty of the plates, and had refused to print from the remainder. This refusal had resulted in a loss of a turnover of at least 100,000 cards to the defendants. On these cards the wholesale profit was 15s. per 1,000, and thus, it was contended, the failure to complete the contract had meant a loss to Sheppard and Company of at least £75.

According to the plaintiffs' case an arrangement was entered into with Mr. Shaefer whereby they contracted to commence the execution of the work upon payment of a certain sum to the plaintiffs. Mr. Shaefer, the work being commenced upon the receipt of the required payment. The defendants paid the sum of £21 in question in two instalments of £7 in July, and another payment of £7 in August. The contract was varied, the plaintiffs thereby agreeing to deliver 40,000 cards instead of 100,000. The 40,000 were delivered, and with that, the plaintiffs contended, the matter ended, the first contract being cancelled.

In reply to his Honour, Mr. Shaefer said that he had not written a letter to the plaintiffs complaining that they had not sent the balance of the cards, whereupon Judge Bray pointed out that the inference from that was that there was a new contract, and that the previous contract was cancelled. His Honour held that a new contract was made, the work to be proceeded with as soon as the defendants paid an old outstanding account, which was settled on August 7, and that the contract was, in fact, completed. Counter-claims were also made by the defendants on the grounds that the plaintiffs had wrongfully parted with the possession of certain plates entrusted to them for the printing of picture postcards, and still retained the plates taken from the negatives, which were the property of the defendants, that the plaintiffs had also retained the other plates, called "The Ghosts of Hampton Court," and by doing so had caused the defendants a loss of £37 10s. at least, estimated on a sale of 25,000 of the cards at a profit of £1 10s. per 1,000, and that the plaintiffs had printed for another person cards from plates which were the property of the defendants, in infringement of the defendant company's rights, and in respect of which substantial damages were asked. For the plaintiffs it was denied that there had been wrongful procedure or infringement of the defendant company's exclusive rights. In the result judgment was entered for the plaintiffs on their claim for £23 6s., with costs. The defendants did not succeed in any of their counter-claims. His Honour non-suited them in regard to the alleged infringement, with leave to apply for a fresh action as to this.

## News and Notes.

THE PORTRAITS by Messrs. Ellis and Walery, in the exhibition of photographs by members of the P.P.A., recently held at the "B.J." offices, have been purchased by the Platinotype Company as specimens of printing on their "Japine" paper.

THE RAJAR CAMERA, offered by Messrs. Rajar, Ltd., for the best print on their P.O.P. received during each month, has been awarded to Mr. J. Maud, of Smiddles Lane, Bradford, whose print was judged to be the best submitted during February. The paper on which the print was made was purchased from Mr. J. Mason, Godwin Street, Bradford.

GEORGE FAULKNER.—In announcing the change of address of this firm of enlargers we wrongly gave the new address as 44, Finchley Road; it should have been 44, Archway Road, Upper Holloway, N.

MR. W. CROOKE AND THE GUM-BICHROMATE PROCESS.—At the annual dinner of the Edinburgh Photographic Society, held on the eve of the annual exhibition, opportunity was taken to entertain the Judges, Mr. J. Craig Annan, Mr. William Crooke, and Mr. Martin Hardie, R.S.A. In replying to the toast of "The Judges," Mr. Crooke, after congratulating the Society on the high standard of its exhibition, said that they had in photography a multiplication of processes. Some of them were purely photographic, others were in a sense mechanical, and others were in a sense artistic. They had the gum-bichromate process, by which a man was assisted to obliterate all the photography possible from his work. (Laughter.) If the minds of those who used it were always properly trained, he had no objection to the work. But he had no sympathy whatever with these gentlemen when artistic errors were made. There was every apology for a man who did a simple, pure, and natural photograph, and, the conditions being against him, who did not get exactly what he would like. That man was trying to do a good thing. The other man was trying to spoil a good thing. He had no sympathy at all with those who used his "bi-gum process" (laughter) and did not know what they were doing. Then in regard to platinotype and other processes, treatment in the negative was a good deal practised. There was nothing to be said against this, provided they knew what they were doing, but it was a dangerous thing to do if this were not so. Those things were all means to an end. They had to remember that grandeur, in the sense of poetical and imaginative creations, was not possible to photography, as, while they could modify the operations of a lens, they could not give it a mind.

AFFILIATION OF PHOTOGRAPHIC SOCIETIES.—The Executive Committee have made arrangements with the Council of the parent society, by which one of their staff, Mr. Philp, has been set aside to devote his time solely to the carrying out of the affiliation work, under the style of Acting Secretary, and under the control of the Executive Committee.

Mr. Philp has been assistant to Mr. McIntosh during the past few years, and is fully acquainted with the details of the affiliation work, and the Executive Committee feel sure the new arrangement will meet with approval amongst the societies.

The affiliated societies' outing has been fixed for Saturday, May 23, to Ayot, near Hatfield. The arrangements are in the hands of Mr. W. Davenport (Bournville Camera Club) and Mr. C. H. Madden (Secretary North London Society), and full details will be sent to secretaries very shortly. It is hoped secretaries will note the date and arrange for their societies to be well represented, so that a successful outing may be assured. Many well-known men in the photographic world are interesting themselves in the gathering, and the occasion will be one photographers should not miss.

"LA REVUE DE PHOTOGRAPHIE," our much admired monthly contemporary, issued by the Photo-Club de Paris, announces that it will appear in future as an annual publication. For the past five years "La Revue" has championed the cause of pictorial photography in a manner which has certainly commended itself to ourselves. It has published choice examples of the best work without comment or sickly appreciation, and for its text has put forward some excellent technical articles. M. Demachy, a moving spirit in the establishment and conduct of the "Revue," wrote us, we recollect, at the outset, somewhat in these words:—"We shall give our readers some sound technical reading, and the pictorial reproductions will be allowed to

speak for themselves." The "Revue" has spared no pains, and, we should guess, no expense in carrying out this policy, and if the experiment has proved too costly, M. Demachy and his conferees may be sure that our regrets are added to their own. In future the "Revue" will be in its annual volume of much the same character as the periodical issue.

## Correspondence.

\* We do not undertake responsibility for the opinions expressed by our correspondents.

\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

### PHOTOGRAPHY AT THE DOVER PAGEANT.

To the Editors.

Gentlemen,—Information has reached me that a firm of local photographers has approached many of the London papers, stating that none but Dover photographers will be allowed to take photographs at the Dover Pageant, and asking to be appointed agents for the London Press. This statement is entirely unauthorised and incorrect. My committee would be most happy to grant facilities to representatives of any newspaper desiring to take photographs for reproduction. I should be most happy to give you any information desired.—Yours faithfully,

H. R. GEDDES, Secretary.

Pageant House, 2, Effingham Crescent, Dover,

March 3, 1908.

### DRYING NEGATIVES WITH SPIRIT.

To the Editors.

Gentlemen,—I was interested to learn from the "Journal" of February 28 that the explanation I offered of the milky appearance often produced on gelatine negatives by drying them with the aid of spirit had already been suggested by Dr. Lüppo-Cramer. Had I been aware of this I should, of course, have mentioned it in my original letter, as it is evident that Dr. Lüppo-Cramer is entitled to any credit for prior publication of the explanation of the phenomenon, though the explanation I offered has been known to, and considered probably the true one by me and a few friends for more than a year.—Yours faithfully,

F. F. RENWICK.

Norland House, Avenue Road, Brentwood,

March 4, 1908.

### PROFESSIONAL PORTRAITURE.

To the Editors.

Gentlemen,—I had no idea when I wrote my guileless impressions of your professionals' exhibition that I should be stirring up a nest of hornets, but the flying out of two of the genus in your last issue tells me that I have unwittingly touched them in tender spots. These two gentlemen appear to think that I approached the show with a stick for no other purpose than mischievous assault. It is not so, as any impartial reader may see by the commendatory remarks upon each exhibitor's work. What I said of retouching was quite evidently said of professional portraiture generally, and as a principle. Even Mr. Turner and the Country Pro. themselves do not gainsay me. On the contrary, they admit it; and, admitting it, they excuse themselves on the ground that the principle is a paying one. Did I say it was not? Did I say that they were unwise to make their "thousands"?

Both these gentlemen imply derogatory things of the public taste. Their position is, that the public wants to be flattered with lies, and only an "infinitesimal minority" "know or care anything about art." Yet Mr. Turner shows pride in the fact that "millions" frequent the studios and accept work from them with pleasure. But if these millions care nothing for art what is it that they "frequent" the studios for? The answer is, for professional photography. Let them, I say. I should like to see every Pro. in country and London making his "thousands a year," but it would not make me believe that the retouching of their portraits into the monotonous stipple texture of old time methods is admirable, nor that tinkering with the facial lineaments is commendable portraiture. I beg to be allowed to uphold these convictions in the face of all this rapid fortune-making.

I never yet met a person of any intelligence who really *liked* the porcelain texture. I have met many who have grumbled at their photographs. One reason of the gigantic fortunes of photographers may be that the public, long suffering and sanguine, don't at first succeed; but try, try, try again. And when they are pleased it is not because they look like porcelain dolls, but because, as Mr. Turner himself explains, clever lighting has made the sitter look his best, and clever posing has made "even the slipshod, slovenly youth look, for a few moments, a man." Therein lies the secret of the whole matter, and professional, amateur, or poor vilified critic, too, might join hands upon it. The critic, however, finds a fist on every occasion. With marked disingenuousness, Mr. Turner culls a collection of phrases from my article, and, callous as to their meaning in their proper context and their meaning out of it, concocts a sounding sentence with them which he presents as my "scathing indictment." As a *journalist* he would have been a Cressus!

He would like to know whether I am fitted by professional experience to be a judge. But is it professional experience that best fits one to judge? Is not the outside view of better value? I may tell him that I have painted a good many portraits, and eke photographed some; but I don't know whether Mr. Turner will consider such experience professional. At any rate, it is more than a "pose in print."

What pains me is Mr. Turner's cruel construction of my remarks, which were framed to foster the best parts of his profession and to raise admonitions for the worst. He calls it "unsympathetic criticism," "ungracious criticism," and "unfriendly nonsense." All these unkindest cuts are so much in the reverse vein of my article that I feel very hurt. From one whose initials, too, are so like my own it cuts to the quick! My only solace is in Mr. Turner's closing remarks, where he, in a sweetly tolerant spirit, says: "No doubt there is a lot to be said for unretouched work, and our critic (no longer unfriendly, mark you) has omitted to recognise the fact that now many hundreds of professional photographers are working on these *happy* and *economical* lines." With you I italicise these last two adjectives. It is all I want, and all I asked for. Mr. Turner himself pours balm into the wounds he has made. I am resigned to the fate that I shall "have been long forgotten" when "scores of British photographers" "will probably be remembered."

When these happy and economical lines are more generally adopted we may hear less of the sorrows and hardships of those poor pro's who find it hard to make a decent living, charm they never so wisely the vain public who like to be made pretty. There may then even be an end of photographers' associations, framed to be "commercially advantageous." For such associations and the efforts of the profession in other ways to wake up trade, as evidenced by the letters and articles in this and other journals, do not entirely bear out Mr. Turner's assurance that the old lines are "quite safe to follow if success in business is the aim in view." F. C. TILNEY.

March 9, 1908.

#### SULPHIDE TONING OF BROMIDE PRINTS.

To the Editors.

Gentlemen,—In spite of the large amount of work that has been done by careful experimentalists on the toning of bromide prints by sulphuretting the black image, the last word on the subject has apparently not yet been said. Generally speaking, the process may be considered to have reached a point of reliability and sureness of result that brings it into line with the ordinary operations of photography, but occasionally it develops surprises that "give us pause," and make papers like those of Mr. Munkman and Mr. Blake Smith apropos and interesting. One of these "surprises" occurred in my own work some months ago, and as it was the cause of considerable experimental work in the same direction as that of Mr. Munkman I was naturally much interested in his paper.

For quite a time I had been using a certain make of bromide paper which had given me general satisfaction, though I had realised that in toning the colour was capricious, notwithstanding the care taken to maintain constant conditions. The "surprises" came when a large batch of prints, from a fresh delivery of paper, after bleaching in an apparently satisfactory manner refused to tone in the sulphuretting bath. The image returned to its former vigour, certainly, but the colour was for all practical purposes still a black. I naturally imagined that some irregularity had occurred

in the working, so fresh solutions of bleaching and sulphuretting agents were prepared, but with the same result, the image always sulphuretting too near the original black. Half-a-dozen different developers were tried, and the black image bleached with most of the well-known bleachers, but in the end the black image returned unruffled. At length I decided upon trying another make of paper, and accordingly got some of a well-known make. This gave prints of perfect quality, and I bleached a small batch in the ferricyanide-bromide formula that had always given me satisfactory results. As I had procured a fresh supply of pure sodium sulphide I had no anticipation of procuring other than very good sepia colour, so when these too sulphuretting back to almost the original black I realised that there was more in sulphide toning than was "dreamt of in my philosophy." I accordingly commenced experiments to find out, if possible, the reason of my failure, confining myself for the purpose to this one brand of paper. I spent the greater portion of two days in trials with every developer and bleacher I could get, and the end was that the paper would not tone at all with amidol and one or two other developers, with metol-hydroquinone I could get a very dark brown, with iron-oxalate they gave a very good sepia. Although the precise bleacher used made no difference to the result in cases where the image returned nearly to the original black, yet in iron-developed prints the colour was more satisfactory when bleached in the iodine bath as formulated by Mr. Blake Smith. The bichromate-sulphuric bath gave quite an unpleasant shade of yellow-brown. After carefully trying this make of paper I was obliged to decide that, although it was excellent for black prints, as it would only tone satisfactorily when developed with iron-oxalate (which I was desirous of avoiding) I could not contemplate using it. Yet another make of paper was procured, which, from the first, yielded eminently satisfactory colours with any developer and with any bleacher.

Here, then, is my experience, and I think it points conclusively to the fact that the nature of the emulsion has considerable influence on the toning capabilities of the print. It was my intention to make experimental batches of emulsion, containing varying proportions of the halides, to get some idea whether this influenced the finished result, but unfortunately, so far, I have not been able to spare the time requisite. As we are ignorant of the makers' formulae of the various papers, we are working without an important factor in the elucidation of these vagaries. It would seem that as the black image is converted into one or other of the halides it is a matter of small importance whether the original emulsion was a pure bromide emulsion or a compound of several halogens, but this, I think, has to be proved.

My experiments were, as I have said, on lines identical with those of Mr. Munkman, and my results corroborate his in most instances. I am of the opinion, however, that the quality of the negative has considerable influence on the finished result. It was a well-known fact when albumen printing was in vogue that the finest colours demanded for their production a negative of good gradation and opacity, and this I believe to be the case with sulphide toning. I have never been able to get such satisfactory colours with prints from over-exposed "flat" negatives, however they were developed and toned, as with those from negatives of perfect gradation and full opacity. When any bromide paper tones readily with the sulphide toning bath, it does seem, as Mr. Munkman states, that the precise developers used have little to do with the result, but my observations go to show that with a given paper some one developer may give richer sepia tones than any other. Iron oxalate in my hands gives exceedingly fine results, and with some papers I have got with edinol superb results, such as none of the other developers would give. Mr. Blake Smith has well pointed out ("B.J.," February 28, 1908) how dependent the tone is upon the quality of the original image, and this should be borne in mind by those who expect to get good rich colours from any kind of black image.

With regard to the character of the sulphide used, I am quite in accord with your own remarks in your issue of March 6. I have used several samples of sodium sulphide, but am unable to detect any influence on the colour of the finished print, though the appearance of the sulphide would lead one to suppose that the legend implying purity, inscribed on the label, was a literary embellishment rather than an actual statement.—I am, Gentlemen, yours faithfully,

G. T. HARRIS.

Sidmouth, South Devon.

## Answers to Correspondents.

- All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.**
- Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.**
- Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.**
- For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.**

### PHOTOGRAPHS REGISTERED:—

**E. Vize**, South Main Street, Wexford, Ireland. *Photograph of James Roche, Champion Boxer.* *Photograph of James Roche with his Two Trainers, Robert Browns and Daniel Kelly.*

**ARIOUS QUERIES.**—(1) Will you kindly suggest some remedy for the separation of gelatine film from its celluloid support in roll films after exposure, and instructions for developing the same? (2) Also some remedy for cracks in collodio chloride self-toning papers? (3) Can you tell me how the tiny microscopic photos usually seen in handles of umbrellas and walking sticks and the like are made, and where the necessary materials therefor can be had? These are small positives on a glass support, about 1.12in. in diameter, with a tiny glass lens mounted thereon to magnify the picture, which attains the size of a C.D.V. when looked through it.—**B. O. J.** (Kathiawar, India).

(1) The cause of the trouble is that in the hot and dry air of India the gelatine has become abnormally dry, and contracted to such an extent that it has separated from the celluloid. The best way we can suggest, if the gelatine film is intact, is to coat the back of it with a thin solution of indiarubber, also a glass plate with the same preparation. When the solvents have evaporated press the two rubbered surfaces in contact, when they will adhere. When the films have been developed, fixed, washed, and dried they can be stripped off the plate and the rubber removed. (2) You do not say whether the cracks (which are evidently due to the Indian climate) occur before or after printing. If the latter, the trouble may probably be got over by adding a small proportion of glycerine to the final washing water. (3) These little pictures are produced by the wet collodion process from ordinary negatives, several very small lenses being used for the purpose. The film is then stripped off the glass, cut up, and mounted on the surface of a small Stanhope lens. These little pictures are mostly produced in Paris, and the apparatus for them is made there. It is probable that Messrs. Marion and Co. will procure all the necessities for the pictures to your order.

**E. BLACKBURN.**—We are quite unable to answer your queries. We are not in the secrets of the two firms named, so cannot tell you the names of the colours they employ. Probably, however, they are mixtures of two, or more, to obtain the tints required. However, they sell the materials ready for use, and we should imagine that it would answer your purpose better to purchase them than attempt to make them for yourself.

**INK DRAWINGS FROM PHOTOGRAPHS.**—I am told that photographs can be traced over with ink and then the photographic bases removed with chemicals, so that the picture looks like a pen and ink sketch, and can be copied and used in printing as such. Can this be done? If so, how?—**SKETCH.**

Yes, the drawing is done in waterproof ink, as supplied by Higgins, or obtainable at artists' depots. The print is then bleached away by solution of mercuric chloride or a mixture of potassium cyanide and iodine, as used for reducing prints.

**ENLARGING.**—Under what conditions is it possible to enlarge by oil lamp or incandescent gas (without a condenser) by the aid of  $\frac{1}{2}$ -plate double extension camera, R.R. lens?—**AMATEUR.**

You must work by reflected light—i.e., illuminate a white surface and reflect the light falling on the latter through the negative. Oil lamps are not powerful enough for this purpose.

The best advice we can give you is to use one or other of the illuminating chambers, made on the above system by Lancaster's, of Birmingham. They can be used with your camera.

**ENLARGEMENTS.**—I have been requested by a firm to do several enlargements for show in their shop windows, to advertise the fact that they do enlargements. (The firm are chemists.) Not having any negatives by me, should I be doing wrong if I copied some picture postcards I have of actresses and made sample enlargements from same?—**IN DOUBT.**

Of course you will. You have no right to copy the cards, whether French or English, as there is certain to be copyright in them.

**AUTOCHROMES.**—Could you kindly inform me (1) is it absolutely necessary to fix an Autochrome after intensification? Will it fade if not fixed? (2) Is there any shutter on the market which is suitable for Autochrome exposures—e.g.,  $\frac{1}{8}$ ,  $\frac{1}{4}$ ,  $\frac{1}{2}$ ,  $\frac{3}{4}$ , 1, 1½, 2, etc.? I know Thornton-Pickard, Unicum, and many others, but you cannot get intermediate exposures like 1½, 2½, 3, etc., with them. I work stereoscopic pictures.—**E. Y. E. N.**

(1) It is best to fix after using the acid-silver intensifier. Ordinary lantern slides treated with this intensifier will stain after a time unless fixed. The function of hypo is to remove traces of silver compounds from the film. We consider it quite essential. (2) We do not think you will find a shutter giving exposures with such small differences, and giving them accurately. You might try Newman and Guardia, perhaps they or other makers of focal-plane shutters could make a shutter of this kind with very wide slit and low tension, but it would have to be of quite special construction.

**J. J. S.**—Of course not. As you were paid for taking the photograph you have no copyright in it.

**H. A. L. N.**—"The Cinematograph." By Cecil M. Hepworth, 1s. (Hazell, Watson, and Viney).

**ARCHER CLARKE.**—The Vellum bromide paper is made by the Leto Company, 3, Rangoon Street, E., and was noticed in our issue of January 24, p. 72.

**METAL PLATE.**—We know no firm doing this work regularly. If you apply to any plate and paper maker you might get a quotation for such emulsion-coated plates.

**GLASS NEGATIVES FROM FILMS.**—Kindly advise how film negatives could be glued or stuck to a glass plate, so as to practically make a glass negative of it. I coated the glass and the film with a gelatine solution, but on drying the film came off.—**A. K.** (Zürich).

If you use the formula for film negatives on page 808 of the "Almanac" the stripped film should be soft enough to adhere to the glass plate. If it does not, flow the glass over with a very thin solution of gum, as directed under "Stripping Glass Negatives," also on p. 808.

**M. E. L. F., Abo.**—Stretchers from Griffith's Steam Works, Eyre Street Hill, Clerkenwell, London, E.C. For cardboards, try Berry and Roberts, St. Bride Street, E.C.

**FIXING PRINTS.**—I should be very grateful if you could give me a practical dark-room test for complete hypo fixation of P.O.P. and bromide papers.—**Q. S.**

We cannot give you any test for fixation. The only practical method is to fix for a time that you know to be sufficient. To ensure perfect fixation it is a good plan to use two hypo baths.

**ENLARGING.**—For making enlarged negatives (x two diameters) from P.O.P. or other smooth surface photos, of which I have no longer the original negatives, will you kindly inform me which of the following two methods will produce the sharpest and best enlargements? (a) To directly make enlarged negatives; or (b) to copy same size and then enlarge negatives. Also, I would feel greatly obliged if you will inform me what is the best type of lens obtainable for copying work (mainly monochrome), varying in sizes from  $3\frac{1}{4} \times 4\frac{1}{4}$  to  $10 \times 8$ ? Also most suitable focus and aperture. I have a  $10 \times 8$  camera, with extension 21 inches, and am getting a Lancaster copying attachment, as shown on page 425 of the "B.J." Almanac.—**J. H. I.**

The first method would be likely to give the sharpest results, seeing that it involves only one operation, but much depends on the lens. As to lens, there are many designed specially for

copying purposes, and you had better consult the advertisements in the "Almanac." We should advise as good an anastigmat as you can afford and the greatest focal length that will suit your apparatus. Aperture is only of importance so far as it affects exposure.

F. H. W.—We refer to the matter again in "Ex Cathedra."

INTERESTED.—There can be no other explanation than that the plate is put in with the glass side to the lens. In that event, a fortunate accident has evidently preserved the sharpness of the faces.

C. H.—We should suspect the mounts as a probable cause, that is, if you adhere to the directions for gold-platinum toning. We advise you to test the mounts as follows:—Lay a piece of paraffin paper or thin celluloid over half the mount, and on this again a silver print (finished but unmounted). Back up with a piece of pure filter paper and several thicknesses of moistened blotting paper, put the whole in a printing frame between glasses (to keep in moisture), and place in a warm place for two or three weeks. If the half of the print in contact with the mount deteriorates before the other the mount may be suspected as defective.

ENLARGING.—1. I wish to know of a satisfactory intense form of illuminant for an enlarging lantern so that small enlargements (say 4 in. x 5 in.) may be printed from  $3\frac{1}{2}$  x  $4\frac{1}{2}$  and smaller negatives on a rapid brand of gaslight (not bromide) paper, and giving only a few seconds' exposure. The Nernst lamp seems disqualified, because in the "B.J." of March 23, page 238, you say the filaments without a diffusing screen show on the paper, and in some past issue I believe I have noticed something to the effect that the carbon points of an arc lamp also show. I have heard of photographers who have and have not had this trouble, and conclude it must be in the type of lamp. If this conclusion is right I would be glad to be advised of a firm where a suitable arc lamp may be purchased, one of the automatic type, which, once a clear disc of light is obtained, no further attention is required. 2. In making small enlargements from a negative which is slightly lacking in contrast, where is the proper place for a yellow screen—between light and condensers, condensers and negative, negative and lens, or lens and easel—to obtain a more brilliant print; and where can the proper article be obtained? 3. Should a negative be placed as close as possible to the condensers, or is there some certain distance for best results? 4. Can you refer me to a popular written article or discussion on how to construct a mechanical device for an enlarging lantern to adjust the lens and easel automatically as the scale of the picture on the easel is altered? 5. Is there on the photographic market a heating device which will keep the developing dish which rests on it at one uniform temperature, and if so, who supplies them?—STUART WATKINS.

1. We cannot trace your reference during the past year or two. A Nernst is an excellent lamp for enlarging purposes, being both powerful and constant, although with it, as with every other lamp, some adjustment is necessary when altering the scale of the enlargement, but not otherwise. Enclosed arc lamps are also very suitable, and are used as largely as any other type of lamp by professional enlargers in this country. You should get prices of the "Westminster" and Jandus lamps and of the Nernst high-power projector lamp, particulars of which have been given in our text and advertisement pages. 2. The usual and most convenient place is on the lens hood. So far as we know, a yellow filter for this purpose is not sold. The more usual plan among enlargers is to use an old lamp for such weak negatives. 3. If placed at a distance in front of the condenser the illumination is stronger, because the area allowed is smaller; but usually the negative has to be placed quite close to the condenser, otherwise the corners are left unilluminated. 4. We cannot give any reference to such an article, but, of course, apparatus constructed on these principles is on the market. If you want really critical focus, we should advise you to rely on ordinary methods of adjustment rather than on mechanical devices, which are excellent in theory, but apt to be unreliable in practice. With practice the trouble of adjustment by hand becomes very slight. The only literature we can refer you to is Cook's patent specification in our issue of May 12, 1905, but you must judge as to the fitness of using the facts in it. 5. We know of none sold for photographic purposes. If you apply to a firm which fits out chemical laboratories you can get a tank provided with a thermostat by which the temperature can be kept constant.

E. EIRNES.—Photo-Revue, 112, Rue d'Assas, Paris.

E. WARR and others.—In our next.

E. B.—The eliminator you name is the best of all in our experience. It might cool the tone of a warm-toned silver print very slightly, but on others, and in the case of bromides, etc., it has no visible effect on the tone.

CONFIDENCE.—As you say, the method has been published, and professional photographers, more frequently some years ago, have introduced the novelty into their business. We suggested a trade mark or trade name for this reason:—You, by pushing the novelty under this trade name, establish a connection with it, so that if any of your competitors take up the idea you can point to your origination of the, say, "Duplex" photographs, and so impress the public that, in this particular instance, you were the pioneer. Your competitor could still take and sell such photographs, but he could not use your fancy name.

A. MARSHALL.—We should expect exposures to be unduly prolonged, and the result inferior to either daylight or a strong artificial light and a condenser. This in the case of a 20 x 16. For 15 x 12 the arrangement would, no doubt, suffice, unless your negatives are unusually strong. In any case, negatives which are right for carbon are bad for bromide enlarging.

W. S.—For a proper rendering of the inlaid work an orthochromatic plate and a fairly deep light-filter are almost necessary. It is advisable to make the exposures out of doors, otherwise the time for each is inconveniently long. Some workers get good results with an unscreened plate, but the most general practice of experts in this work is to use a screen and filter. Practically any maker of ortho plates can supply you with a filter, or advise you as to the best.

PAPER FOR ADHESIVE TISSUE.—Being anxious to purchase on a fairly large scale the thin paper for making adhesive shellac tissue, should be glad of your information as to most suitable material.—J. L.

We are not aware what paper is used by tissue-makers. We suggest your stating your requirements to a maker of raw papers such as O. Rosenstiel, 2, Gresham Buildings, Basinghall Street, E.C., or to J. Spicer and Sons, New Bridge Street, E.C.

THE PHOTO-SECESSION.—An exhibition of drawings, by Miss Pamela Colman Smith, of New York and London; etchings and book-plates by Herr Willi Geiger, of Munich; and etchings by Mr. D. S. McLaughlan, of Boston and Paris, was held at the Little Galleries of the Photo-Seceession, New York, from February 21 to March 11. This exhibition will be followed by examples of the work, in colour and monochrome, of Mr. Eduard J. Steichen, which will be on view from April 1 to 20.

THE LATE A. HORSLEY HINTON.—The "Amateur Photographer," with its current issue (March 10) presents a portrait of the late Mr. Horsley Hinton, by Mr. Fredk. H. Evans, which is justly described as the best ever taken of him. The same issue of our contemporary contains a number of personal and other impressions of Mr. Hinton, by Mr. Alexander Keighley, Alfred Maskell, John B. MacLachlan, Anthony Guest, and A. J. Anderson. It also reproduces a number of Mr. Hinton's best known exhibition pictures.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Photographs of Far Eastern Scenes.—An exhibition of photographs made by Mr. H. G. Ponting, F.R.G.S., opens to-morrow (Saturday) at the house of the "British Journal," and remains open until April 16.

A review of the exhibition appears on page 214, and some notes Mr. Ponting's photographic travels on page 215.

The "B.J." Colonial Number.—Next week's issue will be a specially large number, and will contain reviews of apparatus and materials just coming out to the market for the opening season.

A new printing process in which a permanent silver image is obtained of a warm tone by physical development has just been brought to a commercial stage. (P. 212.)

Two exhibitions now open in London and deserving a visit from photographers is that of "Fair Women" at the New Gallery, and photographs by A. L. Coburn and Baron de Meyer at the Goupil Gallery. (P. 218.)

Which is better:—To take a small negative and enlarge more, or take a larger negative and enlarge less? We try to answer this question for the benefit of the hand-camera worker, who, in each case, must use a lens of large aperture. (P. 211.)

M. Jos Maes recommends a direct reversal method for the production of enlarged negatives. (P. 215.)

The annual meeting of the Professional Photographers' Association took place on the 13th inst. Mr. H. A. Chapman, of Swanwick, has been elected President. (P. 216.)

Frauds and Pests.—We commend the recently issued exposé of fraudulent persons issued from the "Truth" office. (P. 210.)

Fifty pounds was awarded a plaintiff in Westminster County Court Monday for the loss of his wife through a cinematograph exhibition. (P. 223.)

An international cinematograph exhibition will open at Hamburg June. (P. 211.)

Colour photography, ortho' plates, kite cameras, film packs, and also diaphragms are among the patents of the week. (P. 219.)

Echoes of the P.P.A. Exhibition, markings in tank development, non-spherical lenses, and the Ozobrome and Autochrome processes, occupy our correspondence columns. (P. 225.)

## EX CATHEDRA.

### Prof. Lippmann's New Plate.

The article that we published last week from our Paris correspondent describing Professor Lippmann's method of producing stereoscopic photographs without a camera, opens out quite a new sphere of thought with regard to stereoscopy. The first idea that occurred to most readers was, no doubt, Can the resulting effect be truly stereoscopic? and this question is one that at present we should not care to attempt to answer definitely. Some very tangled complications occur when we try to grasp the exact state of affairs. Copying the image on to a second plate of similar structure involves a very curious reassemblage of the multiple images; and the question of viewing distance involves another series of puzzling matters. For example, if the eye can observe only one point in each small image, and if the situation of the eye is that of the original object point, then nothing but that point can be seen in any part of the plate when we look at the original plate developed to a positive. The same conditions must, then, apply to the other eye, if that happens to be situated at the location of another object point, and the net result is that the two eyes see nothing but two overlapping different objects in all parts of the plate. From this it would seem that there must with every plate be a viewing point from which only a confused effect can be obtained. If, now, we attempt to follow up the effect produced when a positive copy is substituted for the original, some very interesting but rather obscure phenomena suggest themselves. No doubt Professor Lippmann has studied these points, which can no longer be obscure to him, so we trust that it will not be long before he treats us to an exposition of the optics of the matter. In the meantime those interested in optical puzzles will find very full scope for their energies in working out the subject for themselves.

\* \* \*

### The "B.J." Colonial Issue.

Our publishers' announcement of the issue of a special number of "The British Journal of Photography" to be placed directly in the hands of photographers in all parts of the world has been met, we are glad to learn, with almost unanimous approval, a consensus of opinion which has justified the wisdom of our publishers in placing a special issue upon a purely commercial basis. Next week's issue will see the fulfilment of a scheme upon which, with the co-operation of friends of the "Journal" in many lands, we have been engaged for the past year, namely, the preparation of a list of professional photographers and photographic dealers outside the circles of our home readers. Our list forms a round of purchasers, too large for any traveller, other than a newspaper, to traverse; a round, indeed, which is the span of the globe itself. The following copy (of the sub-divisions marked on the guide-

cards of our list) made when placing the names with our addressing staff will show the wide extra distribution of the "B.J." for March 27.

Argentine Republic	Malacca
British East Africa	Manitoba
Basuto Land	Mediterranean
Bechuanaland	Mexico
Burma	Natal
British Columbia	New South Wales
Barbados	New Zealand
British Guiana	New Brunswick
British New Guinea	Newfoundland
British North Borneo	North-West Territories.
Bermudas	Nova Scotia
Bahamas	Nicaragua
Bolivia	Orange River Colony
Brazil	Ontario
Cape Colony	Philippines
Ceylon	Prince Edward Island
China	Puerto Rico
Cochin China	Paraguay
Correa	Peru
Costa Rica	Queensland
Cuba	Quebec
Chili	Rhodesia
Colombia	Straits Settlements

Our publishers desire us to say that to-morrow (Saturday, March 21) is the latest time for receiving advertisements to appear in this special issue. We may also remind our ordinary readers that some features of special interest will occupy our text pages. In particular the first of a series of articles on the modern studio and its equipment will appear, and some other features will be apparent when next week's issue comes before its readers.

#### Loss of Density in Fixing.

In May, last year, we referred to a question raised in a contemporary as to the reason of negatives losing density in the fixing bath. The same writer has recently returned to the subject and questions our explanation on the grounds of an experiment that seems to us to be very inconclusive. He copied a print in three sections on a plate, giving one section 15 seconds, the second 30 seconds, and the third 45 seconds. To avoid under-development he left the plate in the pyro developer until the image appeared at the back, and after fixing he found that the first section was very thin, the second of normal density, and the third too dense, from which he concludes that under-exposure is the prime cause of loss of density in the fixing bath. It appears, however, to us that the results do not prove this at all. The resulting print only shows the ordinary effects of under, correct, and over exposure on the same plate, when development is adjusted to the correct exposure. The effect of under-exposure in copying is naturally great thinness of image when development is cut short, and the fact that the image shows at the back of the plate is no proof that all the particles in the thickness of the film are completely developed. As we pointed out in our former note, a completely developed silver particle is not soluble in hypo, except in the presence of oxygen and light. When fixation is conducted in the ordinary way loss of density cannot be attributed to solution of silver, only to the effect of hypo on incompletely developed particles. In the case of the experiments quoted there can be no doubt that the thinness is due to under-development, for the writer states that the part normally exposed showed only normal density when removed from the hypo, and if this was correctly developed it is clear that the more slowly developable under-exposed portion could not have been fully developed. As a matter of fact, a fully de-

veloped under-exposed plate never shows any sign of it in the fixing bath; on the contrary, it is just the kind of plate that shows a maximum amount of density, and gives the effect of what is commonly called "soot" or "whitewash."

\* \* \*

#### The Use of Eccentric Stops.

The ancient experiment of using don't stop with the photographic lens, recently been revived, and we have heard a good deal with regard to the supposed extraordinary properties of "two eyed" lenses and eccentric stops. One of the most popular features of the two-eyed stop is the fact that under certain conditions two dissimilar views can be produced with it; and as these two views can then be combined in a stereoscope it is, of course, assumed that they are stereoscopically dissimilar. It is theoretically possible for them to be so, but in practice serious difficulty arises. The conditions necessary for true stereoscopic effect cannot be fulfilled by Brewster's expedient of cutting two apertures in the cap of a large portrait lens. The "eyes" must be quite differently situated, and it is doubtful if they could be placed in the correct position without using a specially designed or corrected lens. Some examples that have been produced show very violent distortion owing to the wrong placing of the eyes, and it is manifest that two incorrect images cannot combine to give a correct stereoscopic effect. If we think, equally evident that it is not worth while making a large lens that will give the effect correctly seeing that the method at its best is a very inconvenient one. The question of untrue drawing is generally ignored when the stereoscopic question is under consideration, and it is rather amusing to see that another claim is made for the eccentric stop that depends solely on untrue drawing. It is pointed out that by shifting a single stop eccentrically an effect of altered drawing is obtained that cannot be obtained in any other way. As a matter of fact if the drawing is correct with the eccentric stop, the shifting of the stop is exactly equivalent to a corresponding shift of the whole camera, therefore the eccentric stop fulfils no other purpose than that of a fine adjustment of the standpoint. On the other hand, if the effect is peculiar owing to an exaggeration of the drawing, then the idea that the eccentric stops produce a truly stereoscopic pair breaks down altogether. If a correctly situated stop is shifted eccentrically, then, according to elementary laws of optics, any image that is in sharp focus undergoes alteration whatever, and shows no movement. All the strange effects of multiple images, etc., that have recently been described depend on want of focus, and, in the case of solid objects, the varying aspects of the image produced by different eccentric positions of the stop are simply evidences of lack of depth. That this is not generally realised is shown by another remarkable suggestion that has followed upon the revival of these ancient experiments. It is seriously suggested that by placing an agglomeration of stops in front of a lens a useful form of diffusion may be obtained! A much simpler method is to put nothing at all in front of the lens, and leave it to work in its regular fashion, when it will produce precisely the same amount of diffusion. It is remarkable how these simple methods of working get overlooked by authorities in practical photography.

#### "Truth" and Social Pests.

A red-covered sixpenny book just issued from the office of *Truth* and entitled "*Truth* Cautionary List," is one which we can recommend our readers to spend sixpence on although photography—it is satisfactory to see—does not figure in it to any great extent. Its sixty pages of broad details of the great army of the bogus and the fraudulent

do, however, contain one or two references to free enlargement firms, though curiously the P.O.P. formula fraud of which we occasionally hear appears not to have come under our contemporary's eye. But if it warns its reader of the medical quacks, the money lenders, and trick advertisers, and others whose faith in the gullibility of human nature has brought them fortunes, the sixpence spent upon it is profitably expended. As a matter of fact it is a far more interesting book for a railway journey than the average novel or shilling magazine.

#### An International Cinematograph Exhibition.

Preparations for the International Cinematograph Exhibition to be held in Hamburg from June 13 to 28 are now well in hand. The exhibition promises to be of a fairly international and interesting nature. It is the object of the society to give as comprehensive a view as possible of the progress that has been made in recent times, and to give an impetus to the interest that has always been shown in Germany. Besides German exhibits there are to be exhibits from England, the United States, France, Italy, and Switzerland. The exhibits will be classed and shown separately in different departments, which include cinematographs and film industry, photographic manufactures, optics and lantern projections, the latest inventions in lighting, and the literature devoted to the various subjects. A special feature of the exhibition will be the application of the cinematograph as a profitable means of advertising.

#### SOME PROBLEMS CONCERNING DEPTH AND ENLARGEMENT.

In our issue of July 26, 1907, we pointed out that if images produced by different lenses are to be enlarged or reduced to one common scale, then a stop of the same diameter must be used in each case, if the final results are to agree as to depth. Quite recently we have received a query showing that the matter of depth and enlargement is one that puzzles many photographers, and that the general application of the rule above quoted is not clearly understood. The query ran somewhat as follows:—If I make a half-plate negative with an eight-inch lens at  $f/8$ , and a quarter-plate negative with a five-inch lens also at  $f/8$ , and then enlarge both images up to  $15 \times 12$ , which enlargement will show the greatest depth?

This question is one that perhaps few photographers are prepared to answer offhand, yet the rule given provides the answer at once. If the lenses had apertures of the same diameter, the enlargements would have equal depth; but, as an  $f/8$  aperture with a five-inch lens is obviously smaller than an  $f/8$  aperture with an eight-inch lens, it is clear that the enlargement from the quarter-plate must show more depth than the other.

The question can be put in many forms, and though every variation may apparently render the matter more mysterious, yet the rule that equal-size images show equal depth if apertures of equal diameters are employed in producing the original negatives will generally indicate a short route to the answer. There is, however, an important corollary to the question. It is obvious that with two lenses of equal rapidity, the one of shorter focus has a material advantage in the matter of depth when we compare prints made on an equal scale. Consequently it is possible to enlarge on a bigger scale from the small negative and still retain the same depth as that shown by the print from the larger negative. This is a view of the matter that does not seem to have occurred to many, for we very seldom see it mentioned. Here we have a new problem:—Suppose a half-plate negative made with an

eight-inch lens at  $f/8$  is to be enlarged four times, then how much enlargement will a negative made with a five-inch lens at  $f/8$  require to give the same depth in the result? To solve this it is necessary to look at the matter from a new point of view. If the depth is equal in the two enlargements, then a particular point in each must be represented by a disc of the same size, according to the view of depth that commonly prevails. Suppose we assume that the lenses were originally focussed on infinity, and that we confine our consideration to the point representing the nearest object in approximate focus in the image produced by the eight-inch lens. According to the rules by which we calculate this distance—commonly called the hyperfocal distance—that point will be a circle of confusion of a certain diameter. If we calculate the hyperfocal distance for the five-inch lens, using the same circle of confusion, then the closest point in focus will be much nearer, but if we vary the diameter of the circle in direct proportion with the squares of the focal lengths, then we shall obtain the same hyperfocal distance with each lens. For example, if we allow 1-100 in. for the circle of confusion with the eight-inch lens at  $f/8$  the hyperfocal distance is about 66 ft., and it will be the same dimension with the five-inch lens if we allow with that a circle of  $1-100 \times 25-64$ , or 1-256 inch. The diameters of the corresponding discs in the originals are, therefore, as 256:100, or as 64:25, or, as the squares of the focal lengths. Therefore the two images will bear enlargement in inverse ratio to the squares of the focal length, so that the quarter-plate can be enlarged 2.56 times as much as the half-plate. If, then, the half-plate bears four times enlarging, the quarter-plate can be enlarged nearly  $10\frac{1}{4}$  times without showing any greater confusion at corresponding points. As a matter of fact its apparent depth will be greater, for, being a larger print, its corresponding points will look relatively sharper, though they are actually the same size. It must be remembered that the ratios given do not represent those of the final results. If two different images are enlarged to the same size, then, according to a well-known rule, the relative degrees of enlargement must be inversely proportional to the focal lengths of the lenses used to produce the negatives. Equal size enlargements are, therefore, produced if an image from a 5-inch lens is enlarged 8 times and one from an 8-inch lens five times. If, however, we enlarge in the ratio of 64 to 25 it is obvious that the final results will be then the ratio of 8 to 5, which is simply the inverse ratio of the focal lengths. If, then, we produce a  $10 \times 8$  print from the half-plate negative, the print from the quarter-plate will be  $16 \times 12\frac{3}{4}$ .

There is yet one more problem worth consideration. We have studied the conditions necessary to produce equal depth in enlargements made from negatives produced by different lens with apertures of the same actual diameter, and also with apertures of the same ratio number. The apertures may, however, neither be of the same diameter, nor have the same ratio number. Thus, for example, the 8-inch lens may be used at  $f/11$ , and the five-inch at  $f/8$ . What, in these circumstances, are the conditions that give equal depth or—as it may, perhaps, better be put—equal out-of-focus effects in the enlargements?

This problem may be tackled in the same way as the last one. In that we found that when focus varied, while the ratio aperture remained the same, then the relative sizes of corresponding confusion discs in the images were directly proportional to the squares of the focal lengths. If the aperture of one lens is varied, then the disc produced by that lens varies directly with the diameter of the aperture, or, what is the same thing, inversely with the ratio number of the stop used. Therefore, if we take two negatives with the same lens using, say,  $f/16$  one time,

and  $f/8$  the other, the first negative will bear twice the enlargement of the second one, or the scale of enlargement is directly proportionate to the ratio number of the stop. If, then, we produce negatives with two different lenses and with different stops the scales of enlargement will be inversely proportional to the squares of the focal lengths, and directly proportional to the  $f$  numbers. Taking the example assumed, if one negative is produced with a 8-inch lens at  $f/11$ , and the other with a 5-inch lens at  $f/8$  the relative scales of enlargements will be as  $25 \times 11 : 64 \times 8$ , or as  $275 : 512$ , or, roughly,  $2\frac{3}{4}$  to  $5\frac{1}{8}$ . The relative sizes of the results will be as  $5 \times 11 : 8 \times 8$ , or  $55$  to  $64$ , which is not a very great difference. The first will be a  $14 \times 10\frac{1}{2}$  in. print, and the other a  $16 \times 12$  in.

Those who understand simple arithmetical formulæ may like to see the above results expressed in condensed form.

If  $F$  and  $f$  are the focal lengths of two lenses, and  $A$  and  $a$  are the ratio numbers (or  $f$  numbers) of their apertures,

then equal depth or equal want of focus in corresponding parts of the image is secured in enlargements when the negative produced by  $F$  is enlarged  $f^2A$  times, and that produced by  $f$  is enlarged  $F^2a$  times, or, which is the same thing, when the relative degrees of enlargement are as  $f^2A : F^2a$ . This produces images varying in the ratio of  $fA : Fa$ . If the apertures are the same diameter, the  $f$   $F$   

$$= \frac{f}{F}, \text{ or } fA = Fa.$$
 Therefore, the relative degrees of enlargement are as  $f : F$ , which produces images of the same size.

If the apertures are of the same ratio number then  $A=a$ , and the relative degrees of enlargement are as  $f^2 : F^2$ , which produces images varying as  $f : F$ .

If the focal lengths are the same, but the apertures vary, then,  $F=f$ , and the relative degrees of enlargements are as  $A : a$ , and the results then bear the same ratio to one another.

## A NEW PROCESS GIVING PERMANENT SILVER PRINTS BY DAYLIGHT DEVELOPMENT.

[The researches of Mr. Sterry and others having of late drawn attention to the aptitude of the latent image to physical development, we are interested in publishing a short paper by the joint inventors of a process, the chief interest of which is centred on its practical outcome, viz., a paper which prints in a few seconds by artificial light and is developed in day or artificial light to prints which have the appearance of gold-toned P.O.P.s, and are, from their method of production, assured of permanency. The essay will explain the principle of the paper, and the very simple method to be followed in working it. Our own short experience of some of the first samples obtainable has placed us in possession of some excellent prints and no doubt our readers will be interested in awaiting its appearance on the market within the next few months by Synoloids, Ltd., 85, Gracechurch Street, London, E.C. We shall have some further notes to make on the paper in a later issue.—Eds. "B.J."]

To make perfectly clear the subject which we propose to deal with in the following article, we must, in the instance, be allowed to recapitulate some well-known theories and facts relating to the methods of developing the latent image formed by exposure to light of the silver haloids. Two developing methods are distinctly distinguished—the physical and the chemical one.

### Physical Development—Upwards.

1. In physical development the silver haloid remains unchanged by the action of the developer, the image being formed of nascent silver reduced from a soluble silver salt in acid solution by a reducing compound, the silver haloid having on exposure gained the property of attracting and fixing upon itself nascent silver in proportion to the amount of exposure received. In this way the image is built up on the sensitive layer from pure metallic silver in the finest state of division, which again is never deposited on parts where an action of light has not taken place. Hence a physically developed image possesses practically no grain, and does not show any lateral spreading of, for instance, black lines into white. A typical example of physical development is represented by the old wet collodion process, well known for rendering images of such brilliancy, clearness, and vigour as hitherto have been scarcely obtainable by any other means, and therefore still greatly used in all cases where such qualities of the negative are indispensable, for instance, in process work. The sensitive layer in this instance is formed by bathing a plate coated with collodion (guncotton solution) containing iodides, or mixture of the same with bromides, as soon as this coating has just set, in a solution of silver nitrate, whereby the insoluble silver iodide (and bromide) is formed in the film, which at the same time becomes imbedded with an excess of silver nitrate. In development this silver nitrate is reduced by the action of a reducing substance (pyro or ferrous sulphate, in acid solution, with acetic or sulphuric acid), and the nascent silver is deposited

on the silver iodide (and bromide) in proportion to the exposure previously given to the same.

### Chemical Development—Downwards.

2. In chemical development no soluble silver salt is present. The light sensitive silver haloid, embedded in some cementing material—most generally gelatine—is itself attacked by the developer, mostly an alkaline solution of some reducing organic substance, and reduced to metallic silver (more or less impure) in proportion to its previous exposure to light. By some secondary so-called "katalytic" process the reducing action is apt to spread laterally within the layer to portions of the silver haloid, which have not received any exposure to light. Hence, for instance, the difficulty of producing a negative in well defined black lines on clear glass from a black and white line drawing on a dry-plate. In addition, owing to the physical condition of the silver haloid and of the cementing material in which it is imbedded, the image itself shows more or less grain.

The difference between the formation of the image by physical and by chemical development is shown in the following diagram:—

Fig. 1.—Physical Development. Fig. 2.—Chemical Development.

For various reasons it seems better to substitute for the terms "physical" and "chemical" development the terms "surface" development and "layer" development, the meaning of which will readily be apparent from the diagram.

From what we have said above it will be easily understood that surface development is preferable to layer development, and attempts have often been made to adapt the first of these methods

dry sensitive preparations, i.e., gelatine emulsions, hitherto, however, without any practical result, as silver haloids formed in gelatine in this respect behave in quite a different manner from those formed in collodion, owing no doubt to the fact that silver haloids form distinct compounds with gelatine or constituents of the same, these compounds not possessing the property of attracting and fixing nascent silver.

It must be well borne in mind that we are speaking of the development of the latent image, which is not to be confounded with the intensification of an image on P.O.P., printed so far as to show all details, and only lacking in intensity, an operation which is wrongly termed "development." We are well aware of the fact that this process is similar to surface development, but it is not identical. It would, however, cause too great a deviation from our subject to prove this difference in an exhaustive manner, and we must therefore beg acceptance of the statement as given.

#### A New Physical-Development Printing Paper.

We have now found means to overcome all difficulties in the way of physical development of gelatine emulsions by abandoning the use of silver haloids and substituting for them the silver salt of an inorganic acid, which now takes the part of, and exactly as, the silver iodide (and bromide) in the wet-plate process, and by compounding a special type of developer, which at the same time gives a very fine tone to the developed image, and if the emulsion be applied to paper will never allow a black deposit to be formed on the back of the print. In this way this developer advantageously used for intensifying slightly printed copies on P.O.P.

We wish now to state the merits of the new process.

All who have used rapid and gaslight developing papers must now know that a great deal of experience, and in many cases doctoring of the negative, are required to get really satisfactory results. If it were not so, papers of this class would no doubt be much more largely used by professional photographers than they are at present. The uncertainty of exposure and of producing a permanent print of warm tone are no doubt the reasons for dismissing with "development" papers.

All these difficulties cease in using papers and transparency plates coated with the new emulsion together with the new developing compound.

The following will explain the method of working the process: The sensitive layer (be it coated on glossy or smooth matt paper, rough matt, white or tinted, clear or opal glass plates, or any other desired support, for any such can be equally well coated) placed in contact with the negative in subdued diffused light, either daylight or artificial light, no yellow or red light being necessary. The exposure is then made, and here we may mention at the correctness of exposure given to an average negative may be judged from the fact that a trace of the deepest shadows is just visible.

#### Printing by Artificial Light.

To illustrate the sensitiveness of the emulsion we may state that, with a negative of ordinary average density, such as is wanted for P.O.P. printing, the correct exposure is about one second to diffused sunlight or three seconds in the shade at this time of the year. If exposed to incandescent gas at a distance of 12 in. from the light the latter should be screened by tissue paper, or a rotating printing-table used to ensure even illumination. The exposure will be about fifteen seconds. From these statements correct exposure to other sources of light or under different conditions may readily be calculated.

As hinted above, in most instances, if the sensitive layer be directly exposed, careful examination of the print in the same light, as was used for filling the printing-frame, will show that slight traces of the deepest shadows are just visible. This possibility of judging the exposure is of still greater importance when enlarging, as it prevents the waste of large sheets of paper. It must, however, always be borne in mind, when filling the frames

and examining prints or enlargements, that the paper is extremely sensitive to light.

Regarding enlargements on this new emulsion, it may be stated that it is astonishing to see the difference between an enlargement on the new material and one on bromide paper, the first resembling a direct print from an enlarged retouched negative, and possessing the same character as the small original negative. After exposure the prints may be stowed away for days or weeks if properly protected from light and moisture, or developed immediately.

To carry this out, a fresh mixture is made of the developer according to our formula. The developing solution is then placed in a dish, and the exposed paper, without previous washing, placed in it, face upwards. The only necessary precaution is to see that the entire surface of the print is covered by the developer, and that no air-bells are present; otherwise nothing else is necessary, no rocking need be done, and several prints can be immersed at once.

After a short time the image will gradually begin to appear, rapidly gaining in strength. The process has the unique property that as soon as the sensitive layer is thoroughly permeated by the developer, which is signified by the picture beginning to appear, the sensitiveness is destroyed so that development can be carried out, if desired, in broad daylight without any fear or possibility of fogging taking place. Hence no dark-room is required for the new process.

The process is an extremely cheap one, and the importance of it to the profession may be realised when we state that a permanent print, indistinguishable from a gold-toned one, can be printed, developed-toned, fixed, washed, and mounted independent of daylight in the short space of time of five or six minutes. Owing to the entire absence of grain, the new process is most valuable for making transparencies, enlarged negatives, and especially for micrography. The correct time to stop development is just before the desired result of the finished print is obtained, as no loss, but instead a slight gain, in intensity takes place in fixing and drying. The print is immediately placed from the developer into an acid fixing-bath.

Were this procedure adopted with ordinary P.O.P. it would be absolutely fatal to the permanency of the photograph; but in the case of the new paper it is widely different, since the pictures produced consist of pure metallic silver, whilst in the case of P.O.P. the picture is formed by a mixture of metallic silver with the sub-haloids of silver, the composition and properties of which are not precisely understood, but are known to form easily decomposable sulphur compounds in acid fixing-baths. Besides this, we transfer in our case an acid paper from an acid developer into an acid fixing-bath, thus avoiding any possible decomposition of the latter which might take place if the fixing-bath were neutral.

Owing to the extreme solubility of the silver compounds in the paper, fixing is extremely rapid, the prints being perfectly fixed in less than one minute in a bath containing 1 oz. hypo to 20 oz. water. After fixing the print has only to be thoroughly rinsed under the tap, when it is permanent, complete, and ready for mounting. An important difference between our process and other silver printing processes is that the presence of traces of hyposulphite in a photograph by the new method cannot affect its permanency. The cause of this behaviour has just been given.

Owing to the qualities of the developer we use no subsequent toning is required, the appearance of a print or enlargement, done as above stated, being indistinguishable from a picture on gold-toned P.O.P. Rich brown to purple tones are easily secured at will by slightly varying the time of exposure, whilst by keeping to the same time of exposure any desired number of photographs can be produced identical in tone. Any difference in the time of development will not affect the tone, only the density of the image. An over-dense picture can be successfully and easily reduced without altering the tone.

Another feature of the developer is that it will develop a very large number of prints; 4oz. of solution will develop thirty-six quarter-plate prints, and it will not go black, even when exposed to the atmosphere for hours after it has been used for developing.

The deepest shadows are always beautifully transparent and

never clogged. It is also extremely easy to get soft prints from exceedingly hard negatives by simply adapting the time of exposure to the character of the negative—i.e. lengthening it in this case.

YORK SCHWARTZ.  
H. J. MALLABAR.

## THE ORIENT IN WELLINGTON STREET.

PHOTOGRAPHS OF THE FAR EAST BY MR. H. G. PONTING, F.R.G.S.

ON Monday next, March 23, will be opened the latest exhibition of THE BRITISH JOURNAL Office Galleries—one which is the record by a clever photographer of his wanderings in search of the picturesque in Japan, China, India, and Burma. The merit of a display of this sort is first and foremost the entertainment it gives to the large public who are unable to visit the distant lands themselves, but to whom travel is a passion the more insurgent because ungratified.

The gentleman who has furnished these photographs is Mr. Herbert G. Ponting. He was commissioned for the task that has so evidently proved a labour of love. Messrs. Raines and Co. have undertaken the seventy odd enlargements that hang here. There is not a single picture that is without its own special interest. Mr. Ponting has had an eye to the life in these Eastern countries as well as to their architectural and natural scenery. His first is a telephoto view, taken at a distance of twenty miles, of Fuji San, the sacred mountain of Japan, popularised in England thirty years ago when Japanese fancy goods swept in a wave over England. Fuji appears upon nine out of every ten designs by Japanese artists: and the penny palm and paper fans sold on London curbstones invariably bore its triangular snow-capped peak. No. 2 shows it again across the Lake Motosu. In No. 4 its crest overtops a remarkable waterfall, where the water spurts out from the side of verdure-covered cliff through a thousand perforations. One of the most impressive portraits of it is "Mount Fuji Above the Clouds" (No. 11). In this there is a foreground of firs, behind which extends the placid lake and the plain beyond to the foot of the mountain. A long swathing cloud stretches horizontally across the middle of the volcano and above it; in the clearest air the peak lifts its scarified apex, displaying its minutest detail of formation. There is perhaps a greater charm in this view than in another, to obtain which Mr. Ponting underwent many patient pilgrimages. He calls it "Mount Fuji and Kaia Grass" (41). It is sunny and placid. The air is so clear that nothing is lost by distance. In front the graceful Kaia grass is not agitated by the slightest breath of air. Without a sign of man, the vast stillness is highly impressive. Such an aspect is rare, and therefore quite worth the oft-repeated twelve-mile journey, and the hours and hours of waiting necessary to bring the precise moment when the grass was dead still and the mountain unveiled by the slightest haze. In another view we are shown a peep of it between two or three stems. Here the splendid enlargement is on such a scale as to give the sensation of actual size. Pictorially considered, the large horizontal view of the immense slope of the mountain-side exceeds the other versions. The snowy peak is supported by lesser wood-covered heights that reach up before it, and a line of cumulus cloud floats gently across its vast proportions. In this picture the sublimity of its mass is better expressed than in the fuller views.

### The Japanese Lady.

Mr. Ponting has been fortunate in ingratiating himself with a Japanese damsel, to whom even Occidental judgment would hand the apple of Paris. Her face is at once the ideal and the real one of Japan. In its regular oval, its smooth texture, and gentle modelling, one sees at once the prototype of the lady's

face on many a screen and fan, and, it may be added, of the mask. It has an undeniable fascination, and in this particular case the half self-conscious glance and smile of the damsel as she stands in a doorway, robed in the becoming fashion of her country, is all but irresistible. This Mr. Ponting calls "O Tsuné San" (5), but whether this is the lady's name or a vocative yearning of the photographer's, others will be able to decide. She appears again "En Déshabillé" (21)—on this occasion only—for Mr. Ponting, and still again in No. 65, in a copse with an umbrella. Here a fine pose, full of action, has been secured, and a charming picture results. In No. 20 she is "At Home" kneeling and warming her hands before setting the tea.

### Typical Eastern Figures.

Mr. Ponting excels in the seizing of action in figure groups. "The Man with the Rake" (7) is a good example. An old Chinaman, in strong light and shade, slouches along most convincingly with rake on shoulder and basket on back. "A Shinto Priest" (53) steps down with dignified air the stone stairs of his temple. Other examples of good movement will present themselves to the visitor. "The Great Wall of China" is shown in No. 10, where it is seen to be low enough to allow a native to lean over. In No. 31 we are shown the "Walls of the Tartar City," Peking—an elevation of one of the enormous fortifications, with traces of its recent bombardment in the ruined roof. A train of camels, splendidly caught, comes towards us with slow swing from a gap in the outworks. Their path cuts across the antique frontier at right angles.

### Indian Figures and Architecture.

Amongst the Indian pictures is one of "A Fakir of Holy Benares" (64) lying at ease on a bed of sharp three-inch spikes. "Burmese Women Praying in the Paingu Caves" (58) has the most curious effect. The two immense idols appear, somehow, of human size, and the group of women look like a score of little dolls placed before them. Much the same illusion is felt in No. 16, "A Prayer to Buddha," where there is but one supplicant. This is a print of exceptional quality.

The buildings of India have given Mr. Ponting some good opportunities. "The Taj Mahal" (11) is shown against a cloudy sky, which relieves the gleam of its white marble. Some of the Chinese temples show a little undue forcing of effect.

In the shadow of a marble entry stands "A Servant of the Maharajah" (12) chained to a stone, for he is an elephant, and makes a most effective picture.

No. 45, "With the Allies in China," a photograph of a pack of mules being driven along a dusty road, is a wonderful representation of movement, and one sees in it, perhaps at its best, the genius of the photographer for seizing on the very instant when the subject is free from awkward positions which usually turn photographic attempts at movement into ugly records of arrested movements.

Of the landscapes there remains not much to be added to what has been said already of the mountain pictures; but mention may be made of "Tea on the Hills and Rice in the Plains" (66), a Japanese panorama which affords an instructive view of the

parts of the country under cultivation and of the manner of the workers.

### A Touch of Eastern Colour.

Mr. Ponting has very wisely added a few prints in colour. The most pleasing of these are "Under the Purple Wistarias" (40) and "Evening at Matsushima" (50), which gives excellently an outdoor effect. The Purple Wistaria picture is certainly the

most decoratively disposed of any, hence Mr. Ponting made a wise choice in selecting it for colour. Its traditional look is due to the ladies' figures that stand and sit upon a sort of pier made of slight timber and bamboo; a river runs below, and the wistaria blossoming from a broad band of colour just in the approved method of Japanese art.

The exhibition should prove of unusual interest to the public, who may visit it free of charge. F. C. TILNEY.

### A PHOTOGRAPHIC ILLUSTRATOR IN THE EAST—SOME NOTES OF MR. H. G. PONTING'S WORK.

MR. H. G. PONTING, whose photographs of Eastern scenes are now being shown in Wellington Street, is still a young man, and younger still in photography.

A year or two ago he was ranching and gold mining in California, but photography has always been his hobby, or, rather, his best-loved pastime. He had a roving commission to go to the Far East writing and photographing, and was correspondent for "Harper's" with the first Jap army. He was one of the correspondents who received from the Emperor of Japan a medal called the Imperial Order of the Crown with a diploma. All the pictures of Japan, Korea, and Manchuria which appeared in the English and Continental papers before the war, under Underwood's copyright, were his work, as he travelled in those countries with a stereo camera before the war as well as during it. He was, we believe, the only correspondent who was allowed to spend three days on the half-sunk Russian warships in Port Arthur, watching the salvage operations, a few months after the fall of the fortress.

Mr. Ponting has undertaken three different commissions to visit the Far East, and his photographic travels have covered (in the East) Japan, Korea, Manchuria, China, the Philippines, Java, Straits Settlements, Burma, India, and Ceylon, and, furthest west, the Sandwich Islands. His illustrated articles have been published in "Harper's," "The Century," "World's

Work," "Country Life," "L'Illustration," of Paris, "Illustrated London News," and "Leslie's," of New York.

All over Japan he is known as "the Fuji man," a nickname bestowed on him by the Japs, as he has photographed Fuji from more points than any one else. In order to get his two pictures of "Sunset" and "Above the Clouds" from the top of Fuji he was compelled to remain at the summit (12,365 feet) four days and nights, during most of which time the weather was such that it was impossible to stand outside the hut, the force of the hurricane was so great. Mr. Ponting describes Fuji as the loveliest mountain in all the world, and as he has stood on the summit of the queenly Jungfrau, has gazed down on Italy and France from the summit of Mont Blanc, and has viewed Everest and Kinchinjunga in the Himalayas, he may perhaps be permitted to express an opinion.

On the few occasions in his photographic career that Mr. Ponting has entered the western world, where there are such things as photographic exhibitions, he has made his own exhibition prints, but as he is at present away from home, temporarily in London, it has been impossible for him to do so, and therefore he has placed such negatives as he had with him in the hands of Raines and Co., of which enterprising firm he writes in terms of the warmest praise of the care and attention paid to his wishes.

## A METHOD OF MAKING ENLARGED NEGATIVES DIRECT BY REVERSAL.

[The name of Mees being familiar to readers of photographic literature in this country, it may be interesting to state, in translating the following article from the "Bulletin of the Association Belge de Photographie," that the author, M. Jos Maes, is probably a member of the same family as Dr. C. E. K. Mees, who traces his descent from a Dutch or Flemish ancestry on his mother's side. It was M. Jos Maes, if we remember rightly, who, a year or two ago, suggested that the materials for a developer could be measured sufficiently accurately in mustard-spoonfuls, a procedure which we can hardly imagine commends itself to his English kinsman.—Eds. "B.J."]

Of the various methods of making enlarged negatives, the simplest and most rapid is that based on the reversal of the image in a manner somewhat on the lines of that employed by MM. Lumière in the manipulation of the Autochrome plate, and used also in many photo-mechanical workshops, particularly in years gone by, for the duplication of negatives. M. Lalagny, of Paris, has revived the system of late, and I can now recommend it, after having used it with great success for enlarged negatives on plates and papers. The actual enlarging process, either by daylight or artificial light, should be chosen for the convenience of the worker. I myself use an arrangement of two incandescent burners placed on either side of a paraboloid reflector, which gives an absolutely equal illumination to the negative, and proves quite satisfactory for a negative of 7 by 5 inches.\* The negative can be turned with its film in either direction, according to whether the worker desires to have his enlarged negative a facsimile or a reversal of the

original taken. While ordinary dry plates give very good results, the enlarged paper negative may be specially recommended, as it is far easier to produce, and is more handy in use. Moreover, it can be printed from either side, and is therefore available for all kinds of printing processes. The kind of paper which has proved best is the ordinary platino-matt employed for ordinary enlargements. Naturally, a paper of as fine texture as possible will be selected; also, the negative papers made by several makers may be used, but their rapidity, which is practically that of a medium dry-plate, renders them perhaps less convenient in use than the slower bromide paper. The developer found best for the enlarged negative is as follows:

Amidol .....	1 gm.
Sulphite of soda, anhydrous .....	2.5 gm.
Potass. bromide, 10 per cent. solution ...	10 drops.
Water .....	100 ccs.

The image appears in five or six seconds, and development lasts about a minute. The time of exposure should be adjusted to allow of the above times being observed, and in this case the

Messrs. Lancaster, of Birmingham, make a variety of these convenient illuminating burners.—Eds. "B.J."

image should be quite strong enough, and will appear in the film; in other words, the positive print should be a little flat. The enlarged print, whether on plate or paper, having been thoroughly washed—this is a very essential point—we are ready for the reversal process. The print is brought out into white light, either by opening the window of the dark-room or by exposing it to the light from an incandescent burner. This brief exposure is necessary in order to fully impress all portions of the silver bromide which, not having been exposed to light during the first exposure, would not be reduced to metallic silver by the developer. With an incandescent burner at 20 to 30 cm. distance, the exposure should be from thirty to sixty seconds. It will be noticed at this stage that the white film becomes slightly grey and tinted; in the case of platino-bromide papers the tint will appear faintly violet. This need give no cause for anxiety, but is in fact a condition for successful results. Exposure having thus been made, the further work is proceeded with in the dark-room. The print is placed in the following solution:—

Potass bichromate .....	15 gms.
Nitric acid .....	6 ccs.
Water .....	500 ccs.

As soon as the plate has been covered with this solution, the positive image springs out for a moment, the reduced silver is dissolved from it, and at the end of a few minutes disappears completely. The silver image is converted into silver chromate.

The print is then thoroughly washed, to remove the salts of chromium; or instead of a rather protracted washing the following solution, due to M. Balagny, is used:—

Sulphite of soda, anhydrous .....	100 gms.
Bisulphite of soda solution .....	20 to 25 ccs.
Water .....	500 ccs.

Five minutes' immersion of the print in this bath will completely remove the chromium salts, after which it is washed in several changes.

The plate or paper print is then again covered with the amidol developer used in the first instance. It reappears at the end of thirty seconds as a negative, which gains density somewhat slowly, and obtains sufficient intensity in ten to fifteen minutes. It is necessary to continue development up to a point when the image appears fogged and somewhat too vigorous, and then, after washing, the print is fixed in an acid fixing bath in the usual way, washed, and dried.

The paper negatives are somewhat opaque, but they can be rendered transparent by rubbing the backs of them with a tuft of cotton wool soaked in:—

Alcohol .....	2 parts.
Linseed oil .....	1 part.

This is done two or three times, so as to allow the solution to penetrate the paper, and the excess is then wiped off. An enlarged negative is thus obtained having the appearance of being made on a very fine ground glass. A trial of the method will show how easy it is to obtain enlarged negatives possessing all the delicacy and gradation of the original. The method can be warmly recommended to amateurs desirous of preparing an enlarged negative for any of the processes, such as oil, bromoil, and gum-bichromate, commonly employed at the present time.

JOS MAES.

**DEATH OF MR. JOHN GROVE JOHNSON.**—We very much regret to hear of the death on Wednesday last of Mr. J. G. Johnson, the head of the well-known firm of Johnson and Sons, of Cross Street, Finsbury. Mr. Johnson had been associated for many years with the important chemical firm which bore his name, and had witnessed the modern developments which it had experienced in the preparation of photographic developing and other compounds, which during the last few years have come upon the market under the trade mark of "Scaloid."

## THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION. ANNUAL GENERAL MEETING.

THE annual general meeting of the Professional Photographers' Association was held on the 13th inst. at the Royal Photographic Society, 66, Russell Square, W.C., Mr. H. C. Spink, president, in the chair.

The Hon. Secretary having read the report of the committee, in moving its adoption, Mr. Alfred Ellis said that members could see from the report that the work of the association during the year had covered a wide range, and it could be fairly claimed that the objects of the association had been kept well in view. Perhaps the matter that had given the committee the most anxiety was the proposed new Copyright Bill. In the Artistic Copyright Society's original draft the rights and interests of photographers had been ignored, and it was only by persistent sticking to their points that any concession could be obtained. The entire brunt of fighting the battle for the rights of photographers had fallen upon the P.P.A., and not the slightest assistance had been received from outside the association. The sub-committee had been successful, however, in obtaining such modifications of the original draft that if the Bill passed in its present state photographers would have little to complain of. The good work done by the association in the matter of this copyright question alone was a sufficient justification of its existence. In reference to the Employers' Liability Act, Mr. Ellis said a considerable amount of work had devolved upon the committee in making the necessary arrangements with the Fine Art and General Insurance Co. Naturally, with regard to a new and far-reaching Act such as this there was everything to learn. The insurance company knew no more than they, but the matter was taken up in good time, and before the Act came into force they were able to present to their members an arrangement which they felt satisfied was reasonable in terms and covered the entire risk. He thought it a pity that more members had not availed themselves of the opportunity, and feared that some of those who had neglected to insure would find themselves in a bad way when trouble arose.

Mr. H. Chapman, J.P., in seconding the motion, said it was difficult for an association when the work was done in the office and in committee to make known the extent of the good work it was doing. The publication of the report should have the effect of informing professional photographers outside the pale of the association of the benefits they generally, and the members particularly, derived from the association, and he hoped that those present would impress upon their fellow professional photographers the importance of supporting the association.

Mr. S. H. Fry said that when Employers' Liability first came into force there was a general expectation of daily accidents, but as time went on and nothing happened out of the ordinary course there was a tendency to ignore the possibility of accidents. He thought it the duty of the committee to rub it into the members that there was a risk, and that it could only be satisfactorily met by insurance. With regard to the report generally, he hoped the members would consider it a satisfactory record of a year's work, for while the members of the committee thought it an honour to serve it should not be forgotten that a considerable amount of work devolved upon them.

Mr. T. C. Turner (Hull) said, with reference to the exhibition, they were much indebted to THE BRITISH JOURNAL OF PHOTOGRAPHY for their hospitality, but while, in his opinion, the exhibits were creditable to the exhibitors, he thought they did not show to as great advantage as they might have done in a gallery better lighted and less cramped in space. He took exception to some of the criticisms of the exhibition.

Mr. Fry thought it would be generally agreed that the present exhibition was far superior to the previous one, and there was therefore every possibility of each succeeding exhibition showing an improvement.

The Hon. Secretary, in course of a general commentary on the matters dealt with in the report, said probably the least satisfactory feature of the report was their stationary membership. That seventy-five new members had joined was not unsatisfactory, and they must expect a certain percentage of loss from death, resignations, etc., but it was not a thing to make them proud of their profession that fifty-two members would have to be removed from the list who owed two years' subscription, but had accepted during that time all the benefits

membership. Commenting on a letter he had received from one of them, which ran: "Dear Sir,—I wish to discontinue my subscription to the P.P.A."—he said it showed that some photographers must have a curious sense of right and wrong to imagine that an obligation could be wiped out in that summary way. The committee were seriously considering methods of increasing their membership, and hoped their next report would be more satisfactory in this respect. With regard to the free portrait swindle, he said there had been numerous complaints from members, and instructions had been given him to deal with the cases. About sixty copies of the letter for publication, referred to in the report, had been sent to country newspapers, and he believed in most cases had been inserted. He felt quite convinced that the photographers in a locality being canvassed, or two or three of them, or even one, with the expenditure of a little energy and a small expense, could so advertise the methods of these people that their efforts would fail to be remunerative. Their two members' meetings had been most interesting, but considering the number of members they had within convenient distance of Russell Square it was a pity the attendances had not been larger. He hoped to be able to announce a lecture or paper for their meeting in October.

Mr. H. J. Rigden (Bowes Park) said that all those who had spoken were members of the committee, but as an ordinary member he should like to express his appreciation of the large amount of work the committee had performed during the year. There could be no possible doubt of the usefulness of the association to members, or of the value of the association's work to photographers generally.

Mr. E. Hilton (Hunstanton) said he had had occasion to make a claim on the Fine Art and General Insurance Company for a loss by fire, and received a cheque in settlement within forty-eight hours, and on the only occasion he had had to write to the Hon. Secretary was to place a case of infringement of copyright in the hands of the association, and he had a cheque in settlement within a fortnight without any trouble to himself.

The adoption of the report was then carried.

The Hon. Treasurer presented a statement of accounts showing a small balance on the year and £194 to the credit of the association to the bank.

The Hon. Secretary said a statement of the accounts and balance sheet would be sent to each member, with the new Handbook to be issued shortly.

Messrs. Frank Turner and C. St. J. Vaughan were re-elected auditors. The list of officers for the new year was then read:—President, H. A. Chapman, J.P. (Swansea); past president, H. C. Spink (Brighton); members of committee—London; F. A. Bridge, Alfred Ellis, Ernest C. Elliot, S. Herbert Fry, H. Edmonds Hull, Langfrier, Alexander Mackie, Daniel Prodger, Edgar Scamell, Langfries, C. H. Skillman, R. Fellows Willson; country: G. P. Abraham Keswick, T. Birtles (Warrington), J. C. Burrow (Camborne), Hy. J. Comley (Stroud), Wm. Gill (Colchester), W. H. Hawkins (Plymouth), Lankester (Tunbridge Wells), F. P. Moffat (Edinburgh), A. F. Towell (Liverpool), R. W. Robinson (Redhill), T. Rowe (Eastbourne), and the treasurer and hon. secretary are appointed by the committee at their first meeting after the annual general meeting.

In leaving the chair, Mr. H. C. Spink congratulated the association on their choice for their new president. Mr. Chapman had given good proof of his interest in the work of the association by having travelled from Swansea on five occasions to be present at their committee meetings. He thanked the members and his fellow members of the committee for their kindly support during his year of office.

Mr. H. A. Chapman then took the chair and was invested with the presidential badge. He thanked the members for the honour conferred upon him, and promised to do his utmost to build up and extend the usefulness of the association. He hoped to attend every meeting. His first duty was to propose a very cordial vote of thanks to Mr. Spink for the able fulfilment of the duties which had devolved upon him since taking the chair a year ago, and asked his acceptance of a replica of the centre of the presidential badge in gold, the gift of the members of committee, as a memento of his year of office.

Mr. Ellis, in seconding, said Mr. Spink had approached the office of president with considerable diffidence, but they had all been sure that he was able and competent when they invited him to take the chair, and he had proved that their faith in him was well placed.

The Hon. Treasurer would like to add a few words to testify to the appreciation of the members of committee of their past president's leadership. He had followed a succession of strong and able presidents, but he had done well, and had earned his place in their roll of past presidents.

The vote was carried by acclamation.

Mr. C. St. J. Vaughan proposed a vote of thanks to the committee, which was responded to by the hon. treasurer and the hon. secretary; and a vote of thanks to the auditors closed the proceedings.

We must hold over the text of the report of the Committee until our next issue.

Mr. H. A. Chapman, the newly elected president of the Professional Photographers' Association, has been intimately connected with photography since very early days, and his long and varied experience should prove of much service in enabling him to fulfil the duties of such a position. Though an Englishman by birth, Mr.

MR H. A. CHAPMAN, OF SWANSEA.  
Elected President of the Professional Photographers' Association, 1908-9.

Chapman has spent the greater part of his life in Wales. As far back as 1853 he was working the Daguerreotype process in Lincoln, and in 1857 moved to Swansea, where he commenced his professional career. His innate sense of humour and genial disposition soon made him a favourite with the Welsh population amongst whom he has lived up to the present time, and who have testified their appreciation by making him, at various times, Town Councillor, Alderman, Mayor, a member of the Board of Guardians, and Justice of the Peace. As president, therefore, of the Professional Photographers' Association Mr. Chapman adds one more distinction to an already goodly list. The portrait which we reproduce was taken in his own studio at Swansea.

**SOUTHEND-ON-SEA PHOTOGRAPHIC SOCIETY.**—The annual exhibition will be held in the large hall of the Technical School, Southend, from April 21 to 24. There will be four open classes, including one for colour photography (prints or transparencies), and bronze plaques will be placed at the disposal of the judge, Mr. F. J. Mortimer, for award in each class, together with a special silver plaque in the champion class. Exhibitors at the South London, South Suburban, and Catford Societies' exhibitions can have their exhibits transferred to Southend carriage free. The hon. sec. is Mr. John Archer, 24, Ashburnham Road, Southend-on-Sea, from whom further particulars and entry forms may be obtained.

## Photo-Mechanical Notes.

### Drawings for Reproductions.

A recent patent specification (No. 19,721, 1907) of Emile Laporte, 107, Rue Neuveville, Fribourg, Switzerland, describes a process for prints resembling etchings. The process consists, then, in taking a translucent sheet, of which the surface is grained or roughened in order to permit of the artist executing his drawing thereon. The grain thus formed upon the surface which receives the picture having destroyed the transparency of the material of the sheet, it is necessary to restore to the supporting sheet employed its original transparency. The supporting sheet can then serve as a negative for a half-tone or litho plate.

The material of the plate is polished celluloid of the clearest and most transparent kind obtainable. On it is formed a grain close and fine according to the design which the artist wishes to depict. This graining of the sheet of celluloid may be effected by different means. One method of obtaining a convenient graining on the surface consists in sprinkling or spraying with a solution of resin in alcohol. When the alcohol evaporates there remains on the celluloid a grained surface of fine particles, which is very convenient for a highly-finished picture.

To thus fix the drawing, and at the same time restore its transparency to the celluloid, one may have recourse to different means, for example, to dip the sheet of celluloid into a bath of acetone, alcohol, or other suitable liquid. Or one may cover the surface of the picture with acetone, alcohol, or the like by means of an atomiser so as to produce the necessary transparency.

### PHOTO-MECHANICAL PATENTS.

The following patent has been applied for:—

PROCESS SCREEN.—No. 4,740. Improved half-tone process screen. Leon Eustace Smiles, "Cheshunt," Park View Road, Welling, Kent.

## Exhibitions.

### FAIR WOMEN AT THE NEW GALLERY.

THE latest display of the International Society of Sculptors, Painters, and Gravers is called the Exhibition of Fair Women, but it must be admitted that many of the women adorning its walls are not fair in any sense of the word, and the visitor who goes with hopes of a dream of fair women will possibly have a rude awakening. It is a fact that a large proportion of modern pictures do not wear well. Methods of painting and mannerisms of style have respectively dulled the material and spiritual lustre of many. But a few do stand the test of time, rising superior to all changes of ideas of fashion and environment.

It is a principle of the painted and photographed portrait alike that where there is arresting design, good tones, choice colour, and, above all, a record of something really human that goes straight to the spectator's heart; then all those antiquated circumstances which cause the flippant to employ epithets like "guy," "frump," "hideous," and so forth, sink absolutely beneath notice in view of the eternal and universal qualities, or else gain from those qualities a glamour and charm. The present reversion of public taste to early and mid-Victorian costume is largely, if not entirely, due to the best work of the painters of those times, far enough removed now to be fresh to the younger generations. Amongst all, the sound and feeling work of Alfred Stevens, the Belgian, stands out as especially admirable. His "Lady at the Piano" hanging here, is so zealously painted as to put to shame much of the cheap shorthand that passes for accomplishment to-day, when the "single interest" fetish gives such convenient excuse for empty spaces. In Stevens the whole thing is the single interest, sound and modest, and harmonious yet magnificently strong and convincing. His unflinching portrayal of dress, furniture, and the light and shade that reveals or obscures them, combines a roundness and solidity of form with the most advanced impressionism. He gives for a close view what Sargent gives for a view at a few paces. But both feel the same qualities of light upon texture and form, though they offer them so differently—the

one by the patient manipulation of an old master, the other by wizard's hypnotic stroke.

The large triple portrait by Sargent dominates the whole exhibition. These three white-clad ladies—Lady Elcho, Lady Tennant, and Mrs. Adeane—sitting together in sunlight whilst the spacious room behind them is in its proper relative gloom, save for a fleck of wall and picture-frame—this stupendous canvas certainly goes further in recording the beauty of certain natural phenomena than any other painted work, Rembrandt's only excepted, and even his had it not been for Sargent's wizardry of touch.

An exhibition of this sort, where everything preaches its own particular sermon of tone, pattern, or pose, is of the utmost value to photographic portraitists. Not only example and precept is here, but warning too; for in a few cases one cannot but regret a prosaic or unhappy arrangement of sitter and accessories, or an insinuating and eccentric manner of presentment. It may also be seen how often the best artists seem to proceed in directions quite opposed to those of tradition and theory. For instance, in Sargent's full-length Duchess of Portland, and in the seated portrait by Neven Du Mont of the artist's wife, the chief accent is by no means on the face. In the Sargent the brightest and greatest expanse of light is on the lower portion of the dress of the tall figure, and in the Du Mont the head is in comparative tone, shaded by trees over the garden seat where the lady sits with her "owl and pussy-cat." "La Rose," by von Glehn, is a study of broken beams, where the hand catches gleam of light and the face lies in shade.

The infinite variety of arrangements and poses, the differing ideas as to the placing of the figure on the canvas, and other matters of like importance may be studied here to better advantage than in an ordinary exhibition, because other branches of art do not claim attention, and because the pictures shown cover a long period of time and are therefore very varied in their styles. The maker of portraits should be strongly inspired by a visit. Particularly to be recommended is Furse's "Lilac Gown," another sunny exercise of a lady whose face, although in tone, is flooded with reflected light under parasol. The distant garden is a revelation in backgrounds, and the composition is boldly halved across its oval limits by the horizontal line of a hedge. The reticent and accomplished Greiffenhagen's "Mrs. Beresford Ryley" is a most delightful harmony of low-toned colour. Had Whistler painted it, his contentious admirers would have had a fine argument. The same artist's "Miss Sybil Waller" is well patterned. The head with its rich colour and generous painting is largely massed up by the plentiful hair and tells as a fine shape in tone against the background. In Alexander's "Marjorie" we see a whole picture in low and quiet tone from which the face emerges with a fuller and more solid modelling. This is, of course, the general method; but it need not always deal in low tones. An opposite way is that of Chaplin, the brilliant Frenchman, whose portrait of Mdlle. Lemaire has the voluptuous charm of brilliant colour. The hands, so exquisitely painted, lie almost indistinguishable among the stiff and ample folds of flashing silk of their own colour; the white bodice is so delicately harmonised as scarcely to suggest contrast. The head alone, firmly and smoothly painted with despairingly faultless drawing, stands out from a dream of indeterminate pink and white and flesh-tints. The portrait is well known by reproduction, but its captivating colour and execution can only be enjoyed in the original.

Many other works of great charm might be detailed did space permit, but it is impossible to do more than whet the appetite by one or two examples. The visitor will notice with enjoyment certain things by Lavery, Watts, Orpen, Nicholson, Blanche, Potter, Lebach, Besnard, Bonnar, Laszlo, Millais, Leighton, and Duran, and may also be interested to see the bright and ingenuous countenance of the famous Mrs. Evelyn Thaw, dextrously given by Harrington Mann.

The exhibition remains open during the present month—daily from 10 to 6.

### CAMERA PICTURES BY A. L. COBURN AND BARON P. MEYER.

An exhibition of sixty-one photographs has been opened at the Goupil Gallery, 3, Regent Street. Thirty-seven of these are by Mr. Coburn, and are, in our opinion, quite the cream of his work.

residue, by Baron de Meyer, are likewise more effective than anything we remember to have noticed from his hand, and therefore we have no hesitation in pronouncing this exhibition one of the most interesting and artistic shows of photographic work that we have ever seen.

Mr. Coburn includes many of his portraits of well-known people, and among those of chief interest are George Moore, Sargent, Le Sidaner, and C. H. Shannon. These make an appeal because of their unhackneyed subjects. It is interesting to find that George Moore is now a smart, stout gentleman, and that the last trace of his early Bohemianism has gone, apparently for ever. We find it difficult to believe that the bullet head of Sargent, as here given, is not somewhat due to the photographer; but the delicate profile of C. H. Shannon is a refined piece of work. In landscape, Mr. Coburn strikes us as having developed further than in portraiture. He shows a very rare originality in selection of subject. His vision has become matured. We once thought him capable of being proud of his work when it was merely new in aspect. Now he seems to get quite as new a point of view as formerly; but he takes care that it has beauty also. In his "Tunnel Builders" we see the figures of workmen silhouetted against the floating smoke of their labours, and standing upon an eminence of Cyclopean steelwork. It is not only a picture of great charm, but is grimly eloquent of its subject also, as well as effective and impressive. Another remarkable print for subject and originality of view is Mount Vesuvius from Pompeii, showing the volcano wreathed in mists and looming up behind the amphitheatre. "The Sea-Side" is an almost bird's-eye view of Ramsgate sands, teeming with bathers, and lit by an eerie flash of sunlight. An extremely high horizon just permits a glimpse of a stormy sky to show itself. An allegorical mood has beset Mr. Coburn in "Life," which shows an old and sturdy creeper spreading over a wall at the foot of which are two tombs wherein the roots find the death that is their life. We may grant the truth of the fact and the aptness of the allegory; but pictorially it is, perhaps, the print of least value here.

Baron de Meyer is a firm upholder of principles that belong to photography rather than to art. He has in one or two cases marred a most beautiful print by his Quixotic respect for what "was there" when he operated. We are not allowed to forget that his pictures are camera pictures. The most flagrant example of this want of subtlety is in the portrait of a lady, which has a staring and offensive triangle of light just where it drags the attention away from the important element of the picture. In other respects this work is a magnificent performance. We admire most his portrait of "The Lady Ottoline Morrell," a fascinating picture in every respect, and "Pepita, the Little Dancer," has character and grace also. Some of Baron de Meyer's Spanish scenes are of great beauty.

The characteristic of all the work here is its distinguished quality, its thoroughness and sincerity, and its absence of that wish to shock which has not infrequently been an attribute of modern pictorial photography. We congratulate the promoters upon their excellent choice of a gallery and the highly distinguished company in which their pictures find themselves. We recommend visitors not to leave the building without a glance at the dreams of colour furnished by Le Sidaner's Hampton Court and London pictures on the ground floor.

#### NOTTINGHAM CAMERA CLUB.

The following is the list of awards made by Mr. Furley Lewis at the exhibition of the above club, which closes to-day. Open classes: Rose bowls have been awarded to the following:—Class A: A. Benussi, No. 46, "Arco Istria"; Dan Dunlop, No. 82, "Edinburgh Castle from Greyfriars"; Class B: J. S. Atherton, No. 157, "Autumn Leaves"; Dan Dunlop, No. 160, "The Old Professor"; Class C: V. E. Morris, No. 173, "Looking into the Cloister" (debarred); W. A. Clark, No. 182, "The Abbot's Chapel"; Class D: Mrs. R. Dunlop, No. 191, "Chrysanthemums"; Class E: Samuel Manners, No. 216, "Apples"; Class F: H. Wormleighton, No. 23, "Busy Sisters"; J. E. Morris, No. 12, "Looking into the Cloister."

The following have received honourable mention:—Class A: Benussi, No. 45, "Studio, Paesaggio"; T. H. Thorpe, No. 71, "The Mists of Morning"; A. K. Dannatt, No. 51, "The Early Day"; Harry Lindoe, No. 52, "The Deserted Mill"; Oscar Hardee,

No. 38, "Bruges Canal"; A. E. King, No. 20, "Sun and Mist." Class B: F. A. Tinker, No. 133, "Diligence"; Mr. and Mrs. Alfred Bracewell, No. 141, "Reverie"; Mrs. E. Peake, No. 99, "Seeing the World"; A. W. Ward, No. 110, "The Drinker"; C. W. Pearson, No. 127, "Head of an Old Man"; J. S. Atherton, No. 134, "The Fisherwoman"; C. H. Eden, No. 133, "Might is Right"; Harry Lindoe, No. 109, "A Portrait Study." Class C: W. H. Blake, No. 166, "An Old Stairway"; H. Jacob, No. 171, "A Cathedral Door"; C. H. Hewitt, No. 168, "In Canterbury Cathedral"; S. D. Middleton, No. 179, "A Gleam of Sunshine." Class D: G. A. Booth, No. 206, "Gooseberries"; Dan Dunlop, No. 188, "Campanula"; J. Maddison, No. 200, "Reflections." Class E: H. C. Holden, No. 240, "A Portrait," No. 239, "Interior," No. 242, "Flower Study"; H. Burrows, No. 243, "Flower Study"; G. W. McIntosh, No. 231, "Anemones"; W. E. Clifton, No. 221, "The Root of all Evil"; T. H. Jones, No. 224, "Two Sticks." Class F: R. Hancock, No. 6, "Carding Spider Attacking Ermine Moth"; Alfred Taylor, No. 38, "Maggies."

#### FORTHCOMING EXHIBITIONS.

- March 7 to 21.—South London Photographic Society. Sec., E. Pady, 260, Southampton Street, Camberwell, S.E.  
 March 14 to 21.—Sunderland Photographic Association. Sec., W. E. Kieffer, Stirling Street, Sunderland.  
 March 18 to 21.—Nottingham Camera Club. Sec., S. W. B. Vines, 101, Sherwood Street, Nottingham.  
 March 21 to 28.—Midlothian Photographic Association. Sec., Robert Oliver, 6, Murieston Terrace, Edinburgh.  
 March 27 to 28.—Catford and Forest Hill Photographic Society. Sec., T. Browne, 169, Woolstone Road, Forest Hill.  
 March 30 to April 4.—Malvern Camera Club. Entries close March 21. Sec., J. B. Nickolls, The Exchange, Malvern.  
 March 31 to April 4.—Sheffield Photographic Society. Hon. Sec., J. W. Wright, 62, Vale Road, Sheffield.  
 April 21 to 24.—Southend-on-Sea Photographic Society. Entries close April 6. Sec., J. Archer, 24, Ashburnham Road, Southend-on-Sea.  
 April 22 to 25.—Plymouth Photographic Society. Entries close April 14. Sec., Wilfred Grist, The Athenæum, Plymouth.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received from March 2 to March 7:—

- FLASHLIGHT.—No. 4,691. Improvements in photographic flashlight apparatus. Albert Victor Bailey, 55, Chancery Lane, London.  
 COLOUR PHOTOGRAPHY.—No. 4,745. Process of colour photography. Charles Louis Adrien Brasseur, 18, Southampton Buildings, London.  
 ANIMATED PICTURES.—No. 4,829. Improved means for displaying animated pictures and the like. Frederic De Mare, 72, Cannon Street, London.  
 DARK SLIDES.—No. 4,935. Improvements on photographic plate-holders or dark slides. Ernest Luckwill, 88, Chancery Lane, London.

#### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

COLOUR PHOTOGRAPHY.—No. 5,692. 1907. Three negative colour records are taken through orange-red, green, and blue-violet colour filters respectively, and from these three negatives are formed four combination negatives by means of the bleach-out process.

From the before-mentioned three negative colour records three positives are made in the usual manner. Each of these positives

is used in combination or conjunction with a colour light filter. Thus, from the orange-red negative colour record I obtained a positive which is used, combined with an orange-red light filter, and the combination is hereinafter called "red positive."

From the green negative record the "green positive" is made, to be used in conjunction with a green light filter. From the blue-violet negative record a positive is obtained, to be used in conjunction with a blue-violet light filter, and hereinafter called the violet positive.

A special bleach-out tissue is used wherein the fugitive dyes, erythrosine, auramine, methyl green, and aniline violet are made more sensitive to the action of light and are rapidly faded or bleached by rays of light of a complementary colour. This tissue is prepared in the following manner:—Dissolve in spirit the blue-green dye, known as methyl green; to the resultant add a little chloral hydrate, dissolved in spirit, a small quantity of resin similarly dissolved, and to the whole some enamel collodion. This mixture is coated on to a support of gelatine and dried at a warm temperature, obtaining a blue green sheet of sensitive tissue that will bleach on exposure to red light. Make a second mixture, as above described, using in place of the blue-green dye, the red dye erythrosine, and rather less chloral hydrate. This mixture is placed over the blue-green tissue, a thin coat of gelatine between the two tissues acting as an insulator. Also make a third mixture, using the violet colour. This mixture is coated on to a separate support of gelatine; and a fourth mixture or coating, using the yellow dye auramine; a little resin, oil of aniseed, and collodion is placed on the violet tissue, a thin coating of gelatine insulating the two coatings. Thus, as will be understood, there are two sensitive tissues, one composed of red on a blue-green ground, and the other composed of yellow on a violet ground.

The sensitive surfaces of the two tissues are placed in intimate contact and firmly bound together, but in such a manner that the two sheets may be separated when desired.

The total sensitive tissue is placed under or in contact with the before-mentioned red positive and exposed to light, with the result that certain portions become bleached, and a black positive on a red ground is the result.

The sensitive tissue is then adjusted under the green positive, and exposed to light, and a combined effect of the green and red positive is formed. The tissue is next exposed to light under the violet positive, after which the tissue will then display a picture in the colours of the object photographed.

Four combination negatives are next formed from the tissue. The portion of tissue bearing the blue-green and red positive records is placed in contact with a photographic plate or other photographic surface, and covered with a green light-filter during exposure, and thus the red portions of the tissue do not affect the plate, which on development will give a negative from which the printing block for the red colour is made in the usual way.

In order to obtain a printing block for the blue colour, the same portion of tissue is placed in contact with a photographic plate or the like, and exposed with a red light-filter over.

The printing block for the violet colour is made in a similar way, using the other portion of tissue, and a green light-filter, the yellow printing block being obtained by using the same tissue, and a violet light-filter. The tissues carrying the positive records being thin, care must be taken in placing the proper surface in contact with the photographic plate or the like, so that the resultant negative is not reversed from that of the three original negative colour records.

Two claims are: 1. A process for the reproduction of four printing blocks for the reproduction of pictures in colours, by the combination of three negative records with a sensitive tissue wherein four colours are used.

2. In the reproduction of pictures in colour, as claimed, the application of four colours, red, yellow, blue, and violet, approximately corresponding to wave lengths 7000, 5550, 4900, and 4250 (multiplied by 10<sup>-7</sup> mm.) respectively. George Woodiwiss, Cullingworth, Bradford.

**ORTHOCHROMATIC PLATES.**—No. 17,452. 1907. The invention relates to the making of a non-screen plate, for which purpose a quantity of yellow dye, known as yellow filter K, manufactured by Meister Lucius and Brüning, of Hoechst-on-Main, under Patent No. 2,622,

of 1906, is added to and mixed with the emulsion, and the mixture so produced is applied to the plate or film, and allowed to dry thereon, and when dry the plate or film is ready for use.

It is found that by adding about 5 cc. of a solution of yellow filter K (containing about 1 gramme of colouring matter to 40 cc. of water) to 200 cc. of emulsion, a mixture is obtained which is in every way suitable for the purpose of this invention. Thomas MacWalter, Colnbrook, Granville Road, High Barnet, Herts.

**MERCURY-VAPOUR CYLINDER PRINTER.**—No. 21,209. 1907. One, or more, mercury-vapour lamps are supported so that they can be surrounded, or partly surrounded, lengthwise, by a type of copying apparatus, which consists of an outer flexible sheet, of any suitable opaque substance, such as cardboard, thin sheet metal, vulcanite, and an inner sheet of flexible translucent material, such as celluloid, between which sheets the drawing or tracing to be reproduced, and the sensitised paper, are placed, and brought into close contact with each other when the necessary curvature is given, to place them in position to surround, or partly surround, the lamp.

By these means the apparatus can be used either horizontally, as on a table, vertically as against a wall, or in any other desired position; a lamp of the ordinarily well known self-tilting type being preferably used in order to start the illumination.

In order to obtain the desired curvature of the flexible copying apparatus whilst surrounding, or partly surrounding, the lamp, suitable flanges, or metal bands of desired form of curve, are provided, on or by which they are secured in position and the required curve retained. Frederick Wilfrid Scott Stokes, 22, Victoria Street, London, S.W.; and Charles Jennings Hillman, 6, Dyer's Buildings, Holborn, London, W.C.

**DRAWINGS FOR REPRODUCTION.**—No. 14,858. 1907. The object of the invention is to furnish the best surface on which to execute drawings or designs, semi-opaque, grained, or otherwise, such that in the progress of the drawing the work may be erased or changed, and that afterwards the lines may be made immovable upon the surface, and the surface bearing the drawing or design may be easily converted into a transparent support.

Gelatine, Nelson's No. 2, is dissolved in water and poured on to finely ground glass warm, and allowed to set and dry upon the surface from twenty-four to thirty-six hours. The sheet of gelatine is then peeled off and is found to have a sharp grain and to be semi-transparent, well adapted to be placed over a drawing to be copied, and is flexible, and presents an ideal surface for the artist to work upon. The drawing may be erased at will, or scratched out, as may be done with a lithographic stone, or may be worked with a brush or with pen and ink, or as a mezzo tint, up to the next step to be described.

After the drawing is complete, the sheet of gelatine bearing the drawing is flowed over with flexible collodion, which permanently fixes the drawing, and at the same time renders the gelatine support transparent. Both sides of the sheet may be varnished as protection from moisture and handling. Having thus made the film transparent, and having fixed the photographically opaque lines, we now have a transparent positive, which may be applied to a sensitised copper plate or otherwise, used in making accurate reproductions upon suitable surfaces.

In producing an etched plate this drawing is placed in a printing frame, face to face with a coated copper plate, as in the usual half-tone work. Ozias Dodge, Norwich, New London, Conn. U.S.A.

**FILM PACKS.**—No. 19,864. 1907. This invention relates to an improved package of the kind in which a number of photographic films are held in a flat state in such a manner that any selected film may be exposed.

The improved package comprises an envelope, a body telescoping therein and open at the front and a stack of films having tabs for selective engagement of any individual film through the wall, and recesses for selective engagement of the remaining films through the wall of the envelope. The invention further relates to an improved holder adapted to contain a film package of this character and expose the selected film.

To dispense with paper sheets between the films is the principal object of the invention, and there has been embodied in the package and holder herewith illustrated, the idea of withdrawing all of the

films excepting the one to be exposed, which latter remains in the frame or body part of the package, while the other films are held in an envelope part and protected thereby from access of light, the end edge of the stationary or exposing film remaining in its place overlapping the withdrawn films, so that when the envelope is pushed back to close the packet the exposed film slides properly into place with respect to the rest of the films. Magnus Nicoll, 140, West-23rd Street, New York, U.S.A.

**THE CAMERAS.**—No. 22,697. 1907. The invention consists of a light platform from which one or more cameras may be supported, means for suspending the platform from the captive string of a kite or balloon or other accessory extending from a kite or balloon, elongated arms extending laterally from the supporting frame, and an elongated pendulum suspended from the ends of the steadying arms. The frame, its supporting means, and the arms are all made of light strong material, such as bamboo and aluminium, so that very little surface need be presented to the action of air currents. By providing an extremely long pendulum connected to the ends of the arms, the slight disturbing influence of air currents is counteracted and the platform and the photographic apparatus supported thereby will be maintained stable under any atmospheric conditions which may be met. All of the parts of the apparatus may be made of any desired materials, preferably such as will produce both lightness and strength. George Raymond Lawrence, No. 2,647, Magnolia Avenue, Chicago, Ill., U.S.A.

**THE CAMERAS.**—No. 9,433. 1907. One invention consists of an aeroplane or kite, having two parts joined together by struts. Each of these two parts contain sails, forming a rectangular box, open at both ends, and having a triangular extension on each side. The upright struts are held apart by cross stays, which are lashed in position, and are detachable to enable the machine to be rolled up when not in use. When the kite or aeroplane is stood on the ground with the struts in a vertical position, the horizontal plane is a trapezoid, having the angles at each parallel equal. The cord or wire which holds the above described kite or aeroplane captive is also provided with a clamp which will grip it, and which combines in itself the suspension for the camera, arranged so that the latter can maintain a predetermined angle in relation thereto.

Four struts are held together by cross stays and so arranged that when sails are added they form a rectangular box; that at top and bottom are open-ended. This represents in plan a figure composed of four straight lines, having two sides parallel to each other, and two sides of equal length joining said parallels with opposed inclination the one to the other, hereinafter termed a regular trapezoid, the struts being disposed at the angles of the said regular trapezoid.

The cord or wire which holds the kite captive is provided with a clamp fixed to it.

The extension from this clamp is arranged to be attached to a camera in such a way that the camera in relation to the clamp may be maintained at any predetermined inclination. Sydney Thomas Williams, 54, Bouverie Road, Stoke Newington, London, N.

**DIAPHRAGMS.**—No. 4,914. 1907. In this invention a series of lines parallel to one another, and either straight or concentric, according to the type of movement of an indicator, are employed to represent in consecutive order, proportional differences in camera extensions, and therefore also, at the same time, scales of reproductions. Each of these lines are then marked where an indicator attached to the mechanism which actuates the lens diaphragm indicates apertures having the actual  $f$  ratios with which it is desired to work, and the several marks thus experimentally determined indicating on the several lines, the same  $f$  ratios are joined one to another forming lines of equal  $f$  ratios crossing parallel lines of equal scales of reproduction. All that is then required to obtain any  $f$  ratio with any extension, is to adjust the mechanism actuating the diaphragm, so that the edge of its indicator coincides with the crossing point representing the particular size of stop required and the actual camera extension.

When two or more sets of diaphragms are employed one of them is adjusted in the manner described, and the diaphragm, in addition to its cross lines and ratios, has divisions giving the actual

size in fractions of an inch, or other convenient unit, of the diaphragm in any position, the size being known, and the other set of diaphragms having each a pointer and division indicating the

actual dimension. they can readily be adjusted to the desired ratios.

The figure represents an iris diaphragm, and the appliance, each carrying a pointer moving over diagram or scale indicating the  $f$  ratio of the camera's extension, and principal focus, as well as the angle of the stop. Ernest Howard Farmer, 3, Coleraine House, Nassau Street, London, W.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Autochromes of Bluish Tones.

A question has been asked (writes M. Dillaye, in "Photography," at the request of Gaumont and Co.) as to the cause of the blue colouring which predominates in certain Autochrome pictures. The matter seems to me more than ordinarily complex, the predominance of the blue being attributable to very different causes, which appear to correspond with different shades of the blue tint. Under-exposure is one cause. In an Autochrome of white roses, which was badly under-exposed, the white petals were decidedly blue. In this case the blue was a deep tint approaching that of indigo.

The second cause is white light entering the camera. In this case the blue tint takes the appearance of a general violet fog, which shows itself both in the high-lights and in the shadows, but the blue is not as deep as in the previous instance, being more of an azure blue or Prussian blue tint rather than an indigo. The third cause seems to be connected with certain conditions of the lighting of the subject, and this appears to be the most frequent cause. The snow scenes that I have seen, amongst others, have manifested this very plainly. In such a case the blue is of an azure tint or ultramarine, and I cannot help thinking that in some way the defect in this case is connected with the colour-screen itself.

**READING PHOTOGRAPHIC SOCIETY.**—A photographic society has been formed in connection with the Liberal Club at Reading. Although confined to the members of the club, it already numbers twenty-three members, with a fair prospect of doubling this number as it gets into working order. The programme will include bi-weekly rambles, monthly competitions, annual exhibition, etc. The hon. secretary is Mr. W. G. Heather, of 45, Broad Street, Reading.

## New Books.

"Les Produits Chimiques purs en Photographie." Paris: Charles Mendel, 2 fr. 50.

A very useful compilation of the properties of the chemical substances used in photography has been brought together in this form by M. Camille Poulenc. The substances are arranged in alphabetical order, and in each case brief information is given as to their properties, methods of identification, or testing for the most likely impurities to occur in them, and some hints as to their storage and preservation. A few lines are also devoted in each case to their photographic applications. The book includes a number of substances and data which we do not usually find in volumes of this kind already published, and on this account we regard M. Poulenc's work as a really useful, if modest, addition to photographic literature.

**PRACTICAL BOOKBINDING.**—An excellent manual of bookbinding written by a director of classes in the craft, Mr. W. B. Pearce, has been published by Messrs. Percival Marshall and Co., price 1s. net. It forms No. 7 of Marshall's "Practical Manuals," and provides in its 130 pages very precise and practical directions for the amateur bookbinder. One respect in which the author could be commended is for the almost exclusive use of photographic illustrations of the actual operations involved. Half-tone reproductions of the tools and the methods of using them figure on almost every page.

## New Apparatus, &c.

Boots' "Safelight" Lamp. Sold by Boots, Ltd., 29-31, Farringdon Road, London, E.C.

Messrs. Boots, the well-known cash chemists, have placed on the market an improved type of dark-room lamp, examples of which have been sent us for trial from the firm's city offices and warehouse, 29-31, Farringdon Road, London, E.C., to which establishment inquiries as to the trade supply of the lamps should be addressed. The lamp is made in three distinct patterns, one for a paraffin lamp, another for incandescent gas, and a third for electric light, but the principle of all three is the same, namely, the use of reflected light only for the illumination of the working bench and dark-room. Each lamp is built in a semi-circular shape, the light being placed to one side. As a result the illumination which is given by the light filter is of a particularly even character

throughout, whilst the construction allows the lamp to be very easily got at, simply by raising the door, which is placed alongside the light-filter on the front of the lamp. This latter, of course, will serve also for a supply of white light to the dark-room when desired, and for the printing of bromide papers, lantern slides, etc. The lamps are made to take a light filter 10 x 8 in. Those supplied are the excellent manufacture of Messrs. Wratten and Wainwright, series 0, 2, and 3. The first is a bright orange light suitable for bromide work, lantern plates, and slow negative plates; Series 2 is a deep ruby filter for the most rapid ordinary and ortho-

chromatic plates; whilst Series 3 is the dense green safelight which Messrs. Wratten have worked out principally for panchromatic and red-sensitive plates. The construction of the lamps themselves is one which makes for convenience in the dark-room, and we are glad to see a construction which we believe has received commendation from practical workers placed upon the market in such admirable shape. Our own trials of the lamps and filters have satisfied us of their satisfactory character for the purposes for which they are put forward. The illustrations show the pattern of lamp containing incandescent gas, but the other two patterns are substantially identical with it, save for the slight differences necessitated by the electric and paraffin illuminants. The prices of the lamps are as follows:—Paraffin, 9s. 6d.; incandescent gas, 10s.; electric incandescent, 10s.; in each case with one of the Wratten and Wainwright "safelights." Extra safelights are supplied of each of the three series at 4s.

## New Materials, &c.

**HARDTMUTH RETOUCHING OUTFITS.**—Both amateur and professional users of retouching outfits frequently consult us as to convenient tools to employ in their work, and it may, therefore, be of service if we take the opportunity to refer to the excellent materials supplied by the famous Vienna firm of Hardtmuth, which for nearly 120 years has been making pencils, and has at its disposal resources and information which, perhaps, no other firm in the same business can equal. The brushes, pencils, stumps, and crayons are put up in convenient sets, suited to those using them for negative or positive work. Thus the shilling set of four crayons for black-and-white working-up of bromides and similar prints is a useful outfit, whilst a more complete set of materials is obtainable with the black chalk supplied separately and used in holders. Similar sets are put up with an equally nice recognition of the wants of negative retouching, and we cannot do better than refer our readers to their dealers, who will be able to supply them with both the sets and single pencils and other specialties.

## CATALOGUES AND TRADE NOTICES.

**MOULDINGS, FRAMES, AND MOUNTS.**—A most comprehensive list of mouldings, picture-frames, mounts, and cardboards of every description is that just newly issued by Messrs. J. Epstein and Co., 10, Rupert Street, Bristol. It is a profusely illustrated, 56-page catalogue from which the professional can judge for himself the immense variety manufactured by Messrs. Epstein in the way of mouldings and made-up frames. Some very choice designs are among the veneered, Florentine, oak, and antique mouldings, and all the prices appear to be placed at very moderate figures. The same firm also supplies picture-rail mouldings, and even publishes framed pictures of popular subjects. The list includes, too, mounting sundries, such as stains, cardboards, binding papers, medals, diamonds, screw eyes, and picture cord. The list is certainly one to be kept for reference. It is sent post free for six penny stamps.

FOR PHOTOGRAPHING the Winter Palace at St. Petersburg recently an Englishman, Mr. Archibald Cardwell Barker, was arrested and taken to the police station, but was released after inquiries.

"NADAR," photographer, dramatist, aeronaut, and black-and-white artist, who was one of the best-known figures on the boulevards under the Second Empire, and who is still hale and hearty at 88, has just sold for an almost nominal sum to the Bibliothèque Nationale a unique collection of caricatures which he took over fifty years to form. About half of them (writes the "Daily Telegraph" correspondent) are by himself, and the others by dead artists of his generation, of which he is almost the sole survivor. The collection includes 149 drawings, and its range is surprising, for it extends from George Sand, of whom Nadar was a devoted admirer, Henri Murger, Bandelaire, Theodore Banville, Theophile Gautier, Alfred de Vigny, Alfred de Musset (whom Nadar did not like), Michelet, to men yesterday and to-day, like Guy de Maupassant and the artists Zola and Horgnignies. All his sitters Nadar knew, or knows, personally.

## ROYAL PHOTOGRAPHIC SOCIETY.

ING held March 17, Mr. Geo. Lamley in the chair. A lantern e, illustrated by many excellent slides, was given by Mr. Dunning, whose discourse proved most interesting and og and was followed by a somewhat animated discussion.

TRAL TECHNICAL COLLEGE PHOTOGRAPHIC SOCIETY.—At a l meeting of the society, held on March 11, when Mr. V. H. ney took the chair, Mr. E. Clifton, F.R.P.S., of Messrs. Dallmeyer, Limited, delivered a lecture on "The Practice of otography," which, illustrated by lantern slides and examples es, was of a most interesting nature, and was greatly appre- by all present. After a short discussion, a vote of thanks to liffon was unanimously carried.

TEBEN PHOTOGRAPHIC EXHIBITION.—The next northern exhibi- ill be held in the Manchester City Art Gallery during the of January, 1909. Mr. S. A. Coulthurst will act as hon. sec., r. A. T. Lakin as chairman, supported by Rev. H. W. Dick r. J. J. Phelps as vice-chairmen, and Mr. C. Dawson as treasurer.

Our readers will be now fully familiar with this great series of successful exhibitions held alternately in Manchester and Liverpool by the Manchester Amateur Photographic Society and the Liverpool Amateur Photographic Association. Last year's success at Liverpool is fresh in our memory, and we are looking forward with confidence to Manchester in January, 1909.

WOOLWICH PHOTOGRAPHIC SOCIETY.—A lantern evening was held on Thursday in last week, 12th inst., when a member, Mr. J. Borthwick Panting, F.R.P.S., read a paper and showed slides from the work of Mr. H. W. Bennett. The subject was "A Visit to the English Cathedrals." Various periods of architecture were explained with plans and interiors of different cathedrals illustrated upon the screen. Mr. W. H. Dawson proposed a vote of thanks to the lecturer.

## Commercial & Legal Intelligence.

CANVASSING FRAUDS.—At Consett, on March 13, Myers Woolfston and Lewis Brazil were charged on a warrant with obtaining 2s. by false pretences from Joseph Davison Potts, at Castleside, on January 2 last.

Superintendent Murphy stated that the accused travelled about the country and asked householders to let them have small photographs to be enlarged, at the same time obtaining a sum of money on deposit. They got 2s. from the prosecutor, and promised to let him have the enlarged photograph the following week, when the balance of the money was to be collected. Mr. Potts had neither seen nor heard of the defendants since. There were hundreds of similar instances against the defendants. There were forty cases in the village of Castleside alone. Defendants represented that they were canvassing on behalf of the "Fine Art Photographic Company." He (the superintendent) was not in a position to say at present whether such a company was in existence or not.

Prisoners stated that at the time they were employed by a Mr. Miller, who had two or three addresses, but was then carrying on business at 65, Princess Street, Bishop Auckland. They received 9d. commission on each order. In this particular case they did promise the photographic enlargement by the following week, but since then they had ceased to work for Miller, and were travelling for another firm.

Prisoners were remanded.

THE ESTATES of John Donaldson Edward, photographic dealer, carrying on business at 63, Princes Street, Edinburgh, and residing at 13, Bank Street, Edinburgh, were sequestrated under the Scottish Bankruptcy Law on March 5.

EMPIRE BIOSCOPE COMPANY.—At a meeting of members of the Empire Bioscope Company, Limited, held recently, a resolution was passed that the company be wound up voluntarily, and that Mr. Joseph Hood, of Cecil Chambers, Strand, W.C., be appointed liquidator. Creditors should send particulars of their claims to the liquidator by April 20.

THE VALUE OF A WIFE.—At the Westminster County-court on Monday last, Ephraim Starling, of Newmarket, an employee of a Newmarket trainer, claimed damages for the loss of his wife through the alleged negligence of the Gaumont Company in giving a cinematograph exhibition.

Mr. Joseph, counsel for plaintiff, said the instrument was placed near the folding-doors, which formed the only exit, and half of which was only in use. The operator dropped on the floor what looked like a piece of chalk. It was alight, and the operator tried to stamp it out. This brought the lantern down, and it burst into flames. There was a crush and rush in which plaintiff and his wife, to whom he had only been married a year, were separated. In the crush the poor woman was pressed into the flames. When she was brought out to her husband her clothes were burnt off her, and she was terribly injured, her death taking place shortly after her arrival at the hospital. The lantern was mounted on loose boxes, was placed near the only exit, and was not protected by any screen. Plaintiff said defendants paid the expenses of his wife's funeral, which amounted to £11. He had not asked them to do so.

The defendant's counsel suggested that the film caught alight and was carried out of the hall. Then a cry of "Fire! Fire!" was raised, there was a stampede, and the lantern was then knocked down. Captain Simpton, Newmarket Fire Brigade, gave evidence that one of the folding-doors was bolted, and the two cylinders of gas-oxygen and hydrogen—were leaning up against the bolted door. The cylinders fell, and that was the cause of the people being burnt. When the cylinders fell they became disconnected with the pipes and caught light from the burning films.

The jury found defendants were negligent, and awarded plaintiff £50.

**FRAUD BY AN ABERDEEN PHOTOGRAPHER.**—At Aberdeen, on Saturday last, Robert Froest, photographer, 5, Canal Street, Aberdeen, was sentenced to forty days' imprisonment for fraud. The indictment set forth that on February 27, by means of an advertisement in "The Stage," under the false name and address of "Moir, 41½, Union Street, Aberdeen," he pretended that he had for sale certain cinematograph films at the price of £5 10s., but which were really worth double the price, and which would be sent to likely purchasers on approval on receipt of a deposit in security. The advertisement having come under the notice of Carl Mannheim, variety entertainer, 22, Wesley Street, Prudhoe-on-Tyne, Froest thereby induced him to send him by post a letter addressed "Moir," etc., containing a cheque for £3, being deposit in security for the inspection or approval, with a view to the purchase or return of the films, and, failing purchase, to return the cheque, which sum Froest appropriated.

## News and Notes.

**COPYRIGHT IN AMERICA.**—A Supreme Court ruling relative to the copyrighting of pictures has just been made which affects the interests of advertisers, publishers, and photo-engravers, and should have their attention. By the new provisions a picture need not have a copyright notice painted on its surface in order to be protected from reproduction. It has commonly been ruled, before this, that if a painting did not show the notice "Copyright" on it, anyone was at liberty to reproduce it in any form desired. Now the published copies which are to be protected alone need be so marked.

The suit at law which resulted in the above finding was one wherein the proprietor of the Berlin Photographic Company sought to prevent the American Tobacco Co. from using in its business reproductions of Sadler's painting, entitled "The Chorus." The Berlin Company purchased from Sadler the rights of reproduction and secured a copyright. Afterward the picture itself was placed on exhibition in the Royal Academy, the copyright reservation being entered in the gallery sale book, though not placed on the canvas. The original afterwards found its way into a private collection and was reproduced by the tobacco company without the consent of the owners of the copyright, the contention being that absence of the copyright notice on the canvas left the painting open to reproduction by anyone. This was opposed and the court supported such opposition, which claimed that "the statute could not have intended that the original picture be disfigured with the notice." Justice Day, in his decision, said:—

We think it was the object of the statute to require this inscription not upon the original painting, map, photograph, drawing, etc., but upon those published copies concerning which it is designed to convey information to the public, which shall limit the use and circumscribe the rights of the purchaser. It would seem clear that the real object of the statute is not to give notice to the artist or proprietor of the painting or the person to whose collection it may go, who needs no information, but to notify the public who purchase the circulated copies of the existing copyright in order that their ownership may be restricted. There does not seem to be any purpose in requiring that an original map, chart, or painting shall be thus inscribed, while there is every reason for requiring the copies of editions published to bear upon their face the notice of the limited property which a purchaser may acquire therein.

Hereafter responsible publishers, photo-engravers, and lithographers will not reproduce an unmarked picture without securing rights to do so from the artist.

**ARCHITECTURAL AND TOPOGRAPHICAL SOCIETY.**—This society has been founded to make and publish a survey of objects of architectural and archaeological interest in the British Islands. It is proposed to collect and keep for reference in the office of the society measured drawings, sketches, and photographs, together with an outline map showing the positions of places described or illustrated. Those who have the control of ancient buildings are requested to stipulate that copies of any measured drawings or photographs and a record of any alterations or restorations shall be deposited with the society. The publications of the society will include a quarterly journal, to be called the "Architectural and Topographical Record." Each issue of this will contain minute descriptions of ancient buildings, heraldry, and cognate matters within the scope of the society. The hon. secretary is Mr. Wilfrid Travers, of 33, Old Queen Street, Westminster, S.W.

**THE SCOTTISH NATIONAL EXHIBITION, Edinburgh, 1908.** Fine Art Section (Photography).—Those interested in above are invited to apply to the Manager, 45, York Place, Edinburgh, for entry forms, which must be returned with exhibits by April 1. The sections are pictorial, scientific, and historical.

**THE POET LAUREATE** of the "B.J." (an unpaid official we hasten to say) has joined the Convention, so he makes it the subject of his first contribution to our pages:—

The Brussels Convention will be  
The biggest you ever did see,  
For when asked to declare  
If they mean to be there  
The members all answer "oui, oui!"  
And they're practising French, so they say,  
For two or three hours every day,  
So that when they get there  
They may make their friends stare  
With their "très parfait parlez Français."

**THE LATE MR. HORT PLAYER.**—Mr. Jacob Hort Player, whose death occurred suddenly on February 24, from quite early days had made a special study of chemistry, and was responsible for various discoveries facilitating the manufacture of phosphorus. His improvements in the manufacture of this substance realised a fortune of something like £200,000 in seven years. His ingenuity was also devoted to the improvement of fog signalling at sea, in which direction he made a useful and important invention. His services to the scientific world were recognised by his being made a Fellow of the Chemical and Geological Societies. At the time of his death Mr. Player was seventy-four years of age.

**PARTNERSHIPS DISSOLVED.**—The partnership between William Honeychurch White and Thomas Naylor, carrying on business as photographic apparatus manufacturers at 4, Roscoe Street, Bunhill Road, and 24, Denmark Street, Charing Cross Road, W.C., has been dissolved by mutual consent. All debts will be received or paid by Thomas Naylor.

The partnership between Arthur Melbourne Cooper, of Bedford Park, St. Albans, Herts, photographer, and Frank Hawkins Clarke, of Bedford Park, St. Albans, electrical engineer, carrying on the business of cinematography at St. Albans, under the style of the Alpha Trading Company, has been dissolved by mutual consent. All debts will be received or paid by A. M. Cooper.

**"BRIT. J. PHOT."**—The American Chemical Society send us a list of the abbreviated titles used by the Editors of their "Journal" in giving abstracts of papers. "Brit. J. Phot." (THE BRITISH JOURNAL OF PHOTOGRAPHY) is the only British photographic journal in the list.

**A PHOTOGRAPHIC SOCIETY FOR GRANTHAM.**—The art of the camera has numerous followers in Grantham, but up to the present little seems to have been done in the way of combined action or exchange of views on this interesting and useful subject. However, all this is to be changed, and a meeting was held at the Y.M.C.A. on Monday evening last with the view of forming a photographic society. Mr. T. Stow took the chair, and amateurs and others interested in photography were cordially invited to be present.

**WESTMINSTER CITY COUNCIL** has accepted the tender of Messrs. Sale and Beach to carry out what photographic work the authorities may require during the year to end March 31, 1909.

The household water here is very hard; so much so that I had a large tank put up for rain-water. This first filters through a smaller tank in which trays containing gravel and charcoal are

arranged, and this water is laid on in pipers to my workroom, and I use it almost altogether for photographic purposes, boiling it well for making up solutions. I use a plain hypo bath from 2 oz. to 3 oz. to the pint for fixing my bromide, throwing it away each time.

There are a good many gas connections in my workroom (and sometimes a stray leak!), and there is also a large oil lamp or stove lighted all day in winter to heat it; and, of course, it is here the prints are dried. If, however, burning or unburnt fumes were the cause (as has been suggested), why does it not affect carbon tissue, for carbon work proper, which I constantly dry at night in this same room after sensitising?—Believe me, yours faithfully,

Deer Park, Castleknock. Co. Dublin,

H. PERRY.

March 14, 1908.

[The effect you describe seems very unusual, and the only cause we can suggest is imperfect fixing. Try a hypo bath with 4 oz. to the pint, and fix for a longer time, or else use two fixing baths. A print that is not perfectly fixed or not thoroughly washed will not bleach properly as a general rule. As in your case it is the high-lights that refuse to bleach, we suspect imperfect fixation to be the prime cause.—Eds., "B.J."]

### LENS CURVES OTHER THAN SPHERICAL.

To the Editors.

Gentlemen,—My attention has been called to the "Patent News" in the "B.J." of January 17, p. 45, in which there is a description of a method for making lenses by the production of the required curve directly on the glass during its revolution on a lathe. I read it with much interest, because both the instruments for producing the curve and the method of making the lens were known and used by the ancient Greeks.

The Greeks produced their curves "By the revolution of a plane governed in its motion by two powers of control." These powers

Fig. 1.

were three in number:—1. A fixed point (.). 2. A fixed straight line (!). 3. A fixed circle or circular motion (o). By the combination of these powers of control six instruments can be made:—

No. 1. ..	No. 4. .o
No. 2. .!	No. 5. !o
No. 3. !!	No. 6. oo

The instruments drawn and described in the paper I refer to, Fig. 2, p. 46, is No. 2, and Fig. 7 is No. 4. No. 2 was used by the

Greeks for drawing one of their anthemions. No. 4 is a very useful instrument, used by the Greeks and Egyptians for vase lines, oval mouldings, capitals, etc. The accompanying diagram shows some of the forms it produces. There is abundant evidence that the Greeks used their drawing instruments directly on their work. The illustration taken from my "Handbook of the Greek Method" will explain how this was done in the making of vases. The instrument used is No. 6 (oo), which is the highest form of simple controlled motion, and it has extraordinary powers. The principle for the Greek method of making a vase or other solid form may be described thus:—"If the same instrument which is used singly on a plane surface be duplicated and united by a rod passing through the drawing points, this rod will describe upon any solid surface

Fig. 2.

the same curve as would be described by the drawing point on paper. The beauty and accuracy of Greek works are, I believe, largely due to the employment of this method. It is not absolutely necessary that there should be two distinct instruments, so long as there is sufficient thickness in the rods used to ensure stability. H. Gk. M.

It did occur to me in my investigations of Greek forms that the method might be used to make lenses, but as I had no knowledge of the particular curves required I did not carry the investigation further.

It will be very interesting to see what will be the practical result of this present use of the Greek method.

DANIEL WOOD.

Author of "A Handbook of the Greek Method," published in 1889.

March 16, 1908.

### MARKINGS IN TANK DEVELOPMENT.

To the Editors.

Gentlemen,—I was very much interested in your answer to my query of "F. H. W." in your issue of February 21, having considerable trouble with the markings referred to when I took up tank development, and I send you herewith a film which was developed one hour in edinol sodium hydrate, and which you will see, shows them very plainly.

While I have made no very thorough study of the matter, I am convinced that the trouble is more pronounced with some developers than others, and with greatly diluted solutions than more concentrated ones. With the regular twenty-minute Kodak formula pyro I have found no perceptible trace of them.

I had come to the conclusion that these dense streaks or marks were due to a sort of physical development or intensification—something after the nature of that which takes place in wet-plate development—and were built up of silver in some form absorbed by the developer from the surrounding partially or under exposed surface, which, diffusing through the solution, would doubtless cause the case of stand development the dense streak, and the halo with tray development. Of course, this is hardly more than a supposition, and is simply the result of ordinary observation, but the theory advanced by Messrs. A. and L. Lumière, and A. Seyewetz in explanation of their "Process of Photographic Development for the Production of Images of Fine Grain," seems to indicate the possibility of something of the sort taking place. In fact, an attempt to utilise their idea for tank development with paraphenylene diamine—one of the reducing agents

mended in their paper—led to markings so very pronounced as to make it advisable to abandon further experiments in this direction.

In negatives by the wet-plate process the peculiarity is always more or less apparent, and in "half-tone" negatives it has the effect of closing up the dots in these places, which causes considerable trouble in etching, as there again there is a similar tendency, as during this action the dots reduce proportionately faster where the high-lights adjoin the dark tones, owing, doubtless, to a somewhat similar cause as that suggested by you in the case of development, in your answer to "F. H. W."

In making line (black-and-white) negatives on wet plates—where it is desirable that the whites should be as dense as possible—the theory that the image is built up of free silver from the unexposed parts is taken advantage of by surrounding the copy—when it is of such a size that the margins come within the plate—with black paper, or something of a like nature, so as to have as much unexposed surface as possible to aid in building up the image.

Another difficulty I have experienced in stand development has been that unless the plates are turned end for end several times, the lower end of the negative would be considerably denser than the other. I have partly concluded that this is owing to bromide being taken up by the developer from the plate, and gradually settling towards the lower portion of the solution. A tank made with a tight-fitting cover; so that it could be turned upside down, something after the style of the Kodak film tank, would be a decided convenience. I trust that any maker adopting this idea will send me one as a compliment for suggesting it. Perhaps an ideal tank would be one so constructed as to keep the solution or the tank itself in constant motion during development.

As development by the tank method seems to be constantly increasing, I think it would well repay some one with proper facilities and the necessary amount of time at their disposal to give the matter a very thorough study.

W. H. THOMPSON.

Suite 17, "The Linden," Hartford, Conn., U.S.A.

## THE FIXING BATH IN AUTOCHROME WORK.

To the Editors.

Gentlemen,—I venture to write to you to ask if you could help me in a difficulty I have met with in working the Lumière Autochrome process. I find I get no signs of frilling at all through all the processes as far as the fixing bath, but in the first washing after the whole film is covered with star-like blisters immediately, and the film eventually comes off (I wax the edges before developing and they hold on). I tried diluting (five times) the hypo bath with water and no result.

Now, it occurs to me that fixing is perhaps unnecessary, as first development is entirely eaten away by permanganate and acid bath, and the remainder of silver bromide is developed right through to the other side of film. There then only remains perhaps slight traces of silver from the intensification process, and with pure water this would be very little. However, as it would be carbonate or chloride of silver from salts in the water and both are soluble in very weak ammonia, I tried this, but however weak, I found at this stage removed the film in exactly the same way as the first washing with hypo. Can you inform me if fixing is really necessary? It seems to me not. My results have been excellent; but, if fixed, all ruined, while those unfixed are very good.

I should be glad if you could tell me the cause and cure for this trouble, if possible.

I use solutions and washing water all at temperatures as given, and all solutions made up exactly to formulae.

Thanking you in anticipation, believe me, faithfully yours,

A. WINTON GOUTCHER.

Ceres Hotel, Ceres, Cape Colony, S.A.

February 25, 1908.

Your trouble seems to be one of the varieties of frilling that has caused so much annoyance with the early batches of plates. Fixing is certainly advisable after intensification, but it is not safe to wash under the tap directly after fixing. Simply immerse the plate in still water for a couple of minutes, then rinse gently by holding the plate with water from a measure and resoak in fresh

clean water for a minute. Repeat this two or three times and then dry. A too violent method of washing is the only cause we can think of. Possibly a reduction of the alcohol in the first developer will help somewhat. We recommend one-quarter of the quantity given by Lumière, the deficiency being made up with water.—Eds., "B.J."]

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

W. G. D. Busby, 122A, Chepstow Road, Newport, Monmouthshire. Photograph of Newport (Mon.) Postal Staff, 1908.

A. McNab, 8, Battle Place, Langside, Glasgow. Photograph entitled: "Inquisitive pussy."

N. Faithfull, The Studio, Gort, County Galway, Ireland. Photograph of the Peterswell Hurling Club. Galway Champions.

FLASHLIGHT.—Yes; two shallow tin troughs form a convenient arrangement. We should advise about  $\frac{3}{4}$  oz. of powder with lens at  $f/8$ , and ultra-rapid plate. The readiest means of firing is to lay the end of the trail on gun-cotton (from your chemists), and fire the cotton with a taper.

F. C. BRAY.—1. Chrome alum solution 7 oz., hypo solution 7 oz., sodium acetate 150 gr. A 50 per cent. solution of hypo is one containing 1 oz. of hypo in 2 oz. (fluid) of the solution. Therefore the bath as made is half this strength, i.e., 25 per cent.—not over-strong. 2. We should check the action of the bath by testing it with a plate; a waste plate will do. It should become completely clear in, say, ten minutes. 3. We should not regard the bath as giving such great hardening action, but you might try a longer immersion of the prints.

COPYRIGHT.—1. Suppose A photographs group at his own risk and enlarges a figure out of it, reduces that enlargement to cabinet size, registers it, and sells it to the public; B copies that cabinet and makes an enlargement and sells it. Can A sue B for infringement of copyright? 2. A sold copies of the group to those in the group. Does this make any difference? 3. If A was engaged to take the group, and a number of copies were guaranteed at a quoted price, A then made an enlargement of one figure and reduced it to cabinet, and registered it and sold copies, B comes along and makes an enlargement from that cabinet and sells it, can A then sue for infringement or not?—BRIGHTON.

1. Certainly he can. B has no right to copy it. 2. It makes no difference. 3. In these circumstances A has no copyright in the photograph or any portion of it. He was paid, or expected to be paid, for his work, and the person guaranteeing him the copies to be purchased could, we should say, establish proprietorship in the copyright. A should obtain the assignment of it from this person.

ASSIGNMENT OF GOODS.—Can a practising photographer who has made an assignment of his goods on behalf of creditors claim as working tools an enlarger, a 1-l camera, and a half-plate camera which he needs to earn a living?—WORKING TOOLS.

No, decidedly not. You have assigned your goods for the

benefit of your creditors, therefore they are theirs, and you have no claim to any portion of them.

**A. WILDMAN.**—You should apply to an expert, such as Mr. Augustin Rischgitz, The Studios, Linden Gardens, Bayswater, W.

**T. S. (Hallow).**—We think you could obtain a material such as you describe from Messrs. Burnet, Long Acre and Garrick Street, W.C.

**P. W.**—Let them soak in a mixture of spirit of salt (1 part) and water (10 to 20 parts) in an earthenware pan or dish for a day or so. The films can then be easily scrubbed off.

**C. C.**—We doubt if there is one. You might apply to the L.C.C. School of Photo-Engraving, Bolt Court, E.C., or you might get private lessons from Mr. E. W. Foxlee, 22, Goldsmith Road, Acton, W.

**TROPICAL.**—The general impression seems to be in favour of the Argentine or Canada. In either country you should be ready to rough it and to travel about from place to place, otherwise you cannot expect to trade with the scattered population.

**EXPERIMENTOR.**—The fastest plate is usually not the finest in grain, but the very fastest plates are now practically as fine in grain as those half the speed. You can be guided by the Watkins speed list.

**A. E. O.**—You should use distemper colours. We must refer you to the article in our issue of February 1 of last year for the directions for making the mixture and applying it.

**STUDIO QUERY.**—I have a room at my house which I want to use for photography, but as I cannot get the lighting that I should like, I should be glad if you could give me any suggestions to improve same. I have sent a rough drawing of the room, and also the amount of light from windows, and have sent a few samples of the results I have got, in which you can see the faults. It is not possible to get any top light, yet there seems to be a lot of light admitted. I have got the walls and ceiling white-washed, and have used a calico reflector. The photograph No. 1 was taken at 11 a.m., No. 2 and 3 at 2 p.m., and No. 4 at 4.30 p.m., during last week on a dull day. Any assistance that you can give me through the medium of your valuable paper will be gratefully received by, yours faithfully,—**LIGHTING.**

In such a room you should get excellent portraits without difficulty. Many would term it almost an ideal studio for an amateur. We should advise you to stop out all the light from the 6-ft. window, as that is of no use, and would tend to produce false lights. The sitter should be placed more in the middle of the room than shown in the sketch, and the background somewhat in the angle in the 6-ft. angle recess, the camera being placed nearer the window. A good deal of the light at the camera end may be curtailed off with advantage. We may tell you that the chief fault with the examples sent in is bad photography; they are all much under-exposed. Had they been exposed double or three times as long as they were they would all have been much better.

**PULP BOARDS.**—I have a lot of pulp glazing boards, and they are very badly scratched. I should be much obliged if you would give me the names of one or two firms where I can get them re-polished. —**R. W. BROWN.**

We know of no firms that make a feature of re-polishing pulp boards. We should advise you to communicate with the makers of those you have, or the dealer who supplied you with them. If they are, as you say, badly scratched, we doubt if they can be done much with.

**RED ENVELOPES.**—It is evident you must abide by the ruling of the Postmaster-General. If you must use a non-actinic envelope you can select a yellow paper or dark brown, which would answer equally well.

**FIREPROOFING FABRICS** (Reply to "Chemical").—Soak in alum 8 oz., ammonium carbonate  $2\frac{1}{2}$  oz., boric acid  $1\frac{1}{2}$  oz., borax  $1\frac{1}{2}$  oz., water  $2\frac{1}{2}$  quarts.

**PINACHROME.**—1. Can you tell me of any published formula for the pinachrome printing plate? 2. Are special dyes required for use with same? 3. Where are the materials to be obtained?—**S.**

The formulæ have not been published. See the articles in the

"B.J.," October 14 and 21, 1904. 2. Yes. 3. They are not now on the market.

**FERRO-PRUSSATE IMAGE.**—As the gradation obtained by the action of light on the bichromates is remarkable for its evenness throughout the scale, while that of a ferro-prussiate image is decidedly poor in this respect, it would seem to me that if one could convert the former image into the latter it would be a distinct advantage in cases where an evenly graded scale in ferro-prussiate is required. Can you tell me how to do this?—**THREE-COLOUR.**

Ferric ammonium citrate, 10 per cent. solution, 2 oz.; potassium ferricyanide, 10 per cent. solution, 2 oz.; acetic acid, 10 per cent. solution, 20 oz. The well-washed bromide prints are immersed in this bath and well washed until the high-lights are clear. The image is intensified by this treatment.

**TENDER ACCEPTED.**—The Asylums Committee of the London County Council has accepted the tender of W. Butcher and Sons for the annual supply of photographic plates, papers, and sundries.

**PHOTOGRAPHIC TEACHER FOR L.C.C.**—Some time ago the L.C.C. authorised the appointment at the Trade School for Girls of a teacher of photography for six attendances a week at a salary of £110 a year, and of an operator in photography for twenty attendances a year at a rate of £1 1s. an attendance. The consultative committee to which the applications were referred have reported that two of the candidates who applied for the post as teacher of photography are quite competent to fill both posts if appointed for whole time. The Education Committee have concurred in this suggestion, favouring the appointment of a whole-time teacher at a commencing rate of pay of £110 a year, rising by annual increments of £10 to £130 per year instead of the previously approved arrangement, pointing out that by this means a saving will be effected of £21 the first year, £11 the second year, and thereafter savings of £1 a year.

**CINEMATOGRAF EXHIBITIONS AND THE HOME OFFICE.**—The L.C.C. Theatres and Music-halls Committee report the reception by the Home Secretary (Mr. H. Gladstone) of a deputation to urge the necessity for immediate legislation to make it illegal for cinematograph exhibitions to be given in premises not licensed for the purpose. The Home Secretary, in replying to the deputation, said he thought it must be admitted that there was great danger in connection with such exhibitions. Though they had been very fortunate up to the present, they could not shut their eyes to the fact that there might be a very serious accident or even catastrophe, and it was most desirable that legislative powers should be taken to put these unlicensed places throughout the country under proper authority. It was not quite the same point, but in connection with the Children's Bill which the Government had introduced, he was considering whether fresh powers could not be taken to deal with special dangers arising during performances given before children in places which were now, both in London and elsewhere, not under proper control. The present matter was rather different, and might have to be dealt with separately, and he would consider whether it would be possible to deal with it by a short Bill in the current Session. He was well aware of the importance of the matter.

**NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## COLONIAL NUMBER.

A special issue of the BRITISH JOURNAL is posted direct to photographers throughout the British Colonies and foreign countries.

### SUMMARY.

**Latest Photographic Requisites.**—A large proportion of this devoted to reviews of new apparatus and materials just appearing in the British market. (P. 245.)

**Modern Studio.**—A series of articles on the design and fitting premises of the photographer commences on page 231, and completed in about seven or eight weekly instalments.

**Colonial Photographers** should note Mr. A. Mackie's article on page 242, which a useful account is given of the prevailing use of modern photographic printing processes by professional photographers in the colonies.

**Canadian reader** of the "B.J." sends some interesting details of business tactics which at present harass the photographer in that country. (P. 241.)

**Recent Photographs.**—The interest created of late in the oil, emulsion, bromoil and carbograph printing processes should command full reading of the instructions for the use of these methods by Mr. C. Welborne Piper, on page 235.

**New method of printing without light**—the Donisthorpe process—negatives which do not need to be transparent is described on page 242.

**Discussions on Copyright.**—We commence a series of chapters on the important facts of copyright (as they affect a business photographer) in understandable dialogue form. (P. 237.)

**Professional Photographers' Association.**—The annual report on page 242 shows the useful work done by the P.P.A. during the past year.

**Precautions** as to making stock solutions of chemicals are given on page 230.

**Modern plate colour positives, reflex cameras, film packs, etc.,** are the inventions described in "Patent News." (P. 245.)

**Decorative work** in decorative photography by S. Elwin Neame. (P. 239.)

## EX CATHEDRA.

### To Our Readers at Home and Abroad.

In the present number of THE BRITISH JOURNAL OF PHOTOGRAPHY we have to ask the pardon of our good readers for the partial or total eclipse of several customary sections of our pages. When we intimated our intention of reviewing the new introductions coming on the market for the now opening season, our estimation of the probable number of the latter was a good deal below the fact, yet it has been a pleasurable, if somewhat arduous, task to examine and report upon so many photographic products of British origin. For the many new plates, papers, processes, and apparatus which figure in our text and advertisement pages this week confirm once again the supremacy of Great Britain in the photographic markets of the world. The issue, as we have already announced, goes to photographers in every corner of the globe, and while the privilege of being the medium of communication between manufacturers and purchasers is appreciated to the full by editor and publisher alike, there is, as well, a sense of patriotic pride—shared, we have not a doubt, by every British reader—in establishing not merely a record in photographic journalism, but a bond between photographers the world over and the great manufacturing houses whose names are household words in photography.

\* \* \*

### A Word About Ourselves.

As we have said, there is gathered in the present issue reports of the many new introductions on the British market.

In some cases the new articles are variations of well known products; in several instances they are absolutely new departures in photographic processes. All, however, have come under our own personal notice and examination, and for this reason the difficulty of drawing distinctions between competing goods is felt by ourselves as acutely as by any one, since the fact is forced upon us that one manufacture is suited for one particular purpose, another for another, and that no single product can be hailed as the everlasting type of perfection in its particular line, seeing that individual requirements are as varied as human nature itself. And so it comes that we must ask for a careful reading of every page of this issue—advertisements and text—in which occupation our foreign and colonial readers in particular should be assured of considerable pleasure and profit.

\* \* \*

### Sulphide Toning.

The experiences of Mr. G. T. Harris, set forth in our issue of March 13, show, as the writer says, that there are many surprises in sulphide toning. An old trouble is the refusal of a

bleached print to tone at all, even in a fresh strong sulphide bath, a defect which has not yet been satisfactorily explained. In Mr. Harris's case the trouble took a form that is new to us. The sulphide bath "toned" the prints to their original black colour. This experience almost suggests that in this case the sulphiding bath produced the black monosulphide instead of the brown sulphide compound that is ordinarily looked for. Evidently in this case the brand of paper used affected the result, for Mr. Harris states that with another make he obtained eminently satisfactory colours with any developer and any bleacher. Mr. Carnegie has suggested that the brown colour is probably a gelatine compound, so it is just possible that Mr. Harris's experiences may have been due to the use of a paper in which the colloid had been modified in some way. With a non-tanning developer we understand that Mr. Harris obtained brown tones, but with amidol and some other developers the image would not tone. This rather points to a kind of gelatine that, when tanned, would not combine with the sulphide, but, of course, this is only speculation, and experimental work is necessary to determine the point.

\* \* \*

### Stock Solutions.

We have seen lately many references to the advantages of keeping chemicals in strong stock solutions, but it is also very desirable that the disadvantages of too strong solutions should be pointed out. Numerous tables of solubilities are published, and it is evident that many of the stock solutions advocated are founded on these tables, regardless of the fact that quite a number of the salts used in photography are much less easily soluble than the rest, while several recrystallise very readily when there is only a slight drop in the temperature. For example, we have recently seen 50 per cent. advocated as a useful strength for soda carbonate. Boiling is, however, necessary to make such a strong solution, and when made a small drop in the temperature will cause the formation in the bottom of the bottle of a solid block of crystals, which will not be redissolved without considerable trouble. Hypo is also recommended to be kept in 100 per cent. solution, but though this fixing agent is very soluble it does not readily give a solution of that strength. Strong stock solutions are undoubtedly convenient, but it ought to be remembered that salts differ very considerably in their solubilities at different temperatures. The alums are a case in point. We see it advised to keep potash alum in an 11 per cent. and chrome alum in a 9 per cent. solution. That is to say, the potash alum is to be a nearly saturated solution, and the chrome alum about half saturated. Such advice disregards two important points. First, the chrome alum is the more readily soluble of the two, and will make a stronger solution. Second, it will remain in solution at a temperature that will cause the other to crystallise out. If chrome alum is crushed it can readily be dissolved to make a 10 per cent. solution, and this will keep even through a cold winter. Potash alum makes a 10 per cent. solution with difficulty, very slowly if not heated, and it crystallises out very readily when the thermometer falls. In fact, in the winter it will not remain in solution unless the room is constantly kept at a normal temperature. It is a useful strength in the summer, but in the winter 5 per cent. is the strongest solution that can be relied on. Again, twenty per cent. is a useful strength for sulphite of soda, but unless the solution has once been brought up to the boiling point it will crystallise out at a very moderately low temperature. In the case of this salt, however, weak solutions are inadmissible, as they deteriorate very rapidly, as also do weak solutions of the alums and of citric acid.

### PHOTOGRAPHERS' SHELVING.

ONE of the minor photographic business matters is saving of time consequent on having the right thing in the right place. One of the greatest aids to neatness, order, and time-saving is a sufficiency of shelves in the work-rooms. These, to be really helpful, must not only be numerically ample, but must be of the right height and width for their particular purpose, and be put in the most convenient place. Shelves, as usually erected by the carpenter, are very wasteful of room. In a new business it is generally better to have some temporary arrangements for a month or two; at the end of that time a good idea of the most useful places for shelves will have been formed, and in all probability the working space will be enlarged instead of encroached upon. To erect shelves is no difficult task, or one requiring many tools, so that a sort of job may be economically undertaken during slack seasons.

Shelf-room for "finished-order" negatives is one of the most insistent and growing necessities of a studio. Shelves must of necessity be strong and securely fixed to the floor and wall. The end uprights, and as many of others as possible, should be arranged on the joists supporting the floors, whilst if the wall be brick, it must be securely plugged and the uprights fixed to it with bolts. The shelves need only be very narrow, so very little floor space is occupied.

If the majority of negatives are half-plates, five and a half or six inches is ample width, and will do equally well for quarters. For whole-plates eight inches is a good measurement. For the former size three-quarter plates a floorboard, with the tongue ripped off with a chisel, afterwards run over with a jack-plane, is good material, being ready planed, and five and a half inches wide. An extra inch is needed on account of the paper wrapping. We might say here that it is advisable to store negatives standing on their narrow side, as the necessary data will be more easily read on the long edge. If written on the ends, the refolding of the paper cover after a re-order has been withdrawn often displaces the writing: this is so liable to happen if done as advised, since the cover being more sharply defined, the negatives are easily justified to it.

The shelves should not have more than three feet space or they will sag with the weight, and too much space between shelves is generally wasted. Two inches to allow the hand to grasp top of packet for removal is sufficient.

A bottom shelf two inches from the floor should always be provided, or otherwise the packets resting directly on the latter will get wet when the floor is washed.

In workrooms there is no need to cover in the front of the shelves, since the paper packets are sufficient protection from dust. Should some wall-space be utilised, however, where customers can see, appearances must be considered. A curtain of art serge, harmonising with the general colour-scheme, and hung on an iron rod, will do, but some sort of door is better. At very slight cost one can make some frame doors, the panels, instead of being of wood, being formed by tacking fabric similar to that covering the walls of the apartment, on to the inside of the skeleton doors. To keep out dust, which dirties the fabric, some thick brown paper is tacked on at the same time. The wood may be stained, as this looks better and is cheaper than if painted, though paint must be resorted to when the stain gets shabby. In the case of these shelves to which we are now referring, the lowest shelf is three feet from the floor, so that accessories, chairs, tables, etc., of various periods can go close back to the wall. These latter take up a lot of floor-space, and make the moving of backgrounds difficult, so in one place a wide shelf may be made that

om the floor, and above that again another six feet  
he floor. The most used articles are kept on the  
a table or chairs, not so useful, are placed on the  
and on the one above such things as are not much  
ed; space is thus trebled. This sounds unsightly,  
the uprights are well-designed, say, tapering at top

and fitted with caps, whilst some of the new-style orna-  
ment is adapted to some decorative splats, the effect can be  
made novel and quite presentable.

We must defer some further notes (and drawings of  
shelves which have been found of practical service) until a  
later issue.

## THE MODERN NOTE IN THE DESIGN AND FITTING OF PHOTOGRAPHIC PREMISES.

### I.

nder this title we commence, with the following article, a  
series of chapters by Mr. Drinkwater Butt, F.R.P.S., on the  
design and decoration of his place of business, and in the  
apartments. Photography being essentially an "artistic"  
business, taste and style need to be more in evidence than in  
other trades. Therefore, while it is not possible to  
prescribe any plan which can be followed in particular cases,  
the photographer can take advantage of them in giving his establishment, both  
weight with his townspeople, and must turn out to his commercial  
on such adornment of the studio, but in these articles Mr. Butt  
moderate way of business need not consider beyond his means.  
particular materials may be used, even on the smallest scale, in  
conveniently be divided into four sections:—

I. Shop-front and Show-case. II. The Reception-Room.  
III. The Studio. IV. Planning complete Premises.  
The last chapter will consist of a description of as complete a set  
of photographic premises as can be imagined—an  
establishment, in fact, which but few living photographers  
would feel justified in putting up. Yet the scheme in its various  
parts may be commended to the study of even the small  
photographer, on account of its detailing arrangements which  
are abstracted in pieces from their surroundings and utilised  
with advantage in businesses which are anything but  
efficient in size. We need only add that all the plans and drawings are Mr. Butt's own work, embodying the experience of  
practice as an architect of studios, and with this explanation we will leave Mr. Butt himself to his readers.—Eds. "B.J."]

curious fact that the enormous advance which the last  
half of a century has seen in the fitting and furnishing of  
all classes of buildings should have so little affected those

premises designed by Mr. C. H. Quennell for Messrs. Speaight  
in New Bond Street; but among the rank and file of the great  
army of what may, without offence, be styled the middle-class

Fig. 1.—For a large city business. To be executed in stone or brick.—Elevation.

to the commercial applications of the art of photography.  
America, it is true, some of the more prominent professional  
photographers, such as Strauss of St. Louis and Falk of New  
York, have had well-designed and finely decorated places of  
business especially erected for them, and in London also we  
have seen very architecturally dignified and artistically fitted

photographers, many of them carrying on good and remunerative  
businesses, things remain very much as they were years ago, and  
we often have the very incongruous spectacle of very artistic  
work being produced amid very commonplace and inartistic sur-  
roundings. A somewhat considerable experience as an adviser  
on the building and fitting up of studios, etc., has led the present

writer to the conclusion that this state of things more often exists by reason of "a want of thought rather than a want of art" (if one may paraphrase in a slightly Cockney manner a well-

ness premises strikes a public that is nowadays used to artificially designed and decorated emporiums of all kinds, as poor, mean-looking, and generally behind the times.

Fig. 1.—Plan.

Fig. 2.—For a good town business. To be executed in oak or painted or stained wood.—Elevation.

Fig. 2.—Plan.

known line), and it is often evident to him that long association has in many cases so blunted the perception of many photographers as to what their places actually look like to a fresh eye, that they do not at all realise how the appearance of their busi-

ness premises strikes a public that is nowadays used to artificially designed and decorated emporiums of all kinds, as poor, mean-looking, and generally behind the times. It is for the purpose of directing more attention to this important matter that the following pages have been written, the suggestion of the Editor of the "B.J." In them it is proposed to refer to some of the general principles which should

ern the fitting and decoration of buildings of this class, and give some hints on those points in which it appears to the reader that improvements on present conditions could often be easily and inexpensively effected.

Perhaps in this first article I cannot do better than give one or two examples of the designs which may be adopted by a photographer erecting a place of business or converting existing premises to his own use. The reader is asked to keep these before him until next week, when I shall revert to my main object, namely, to giving some advice on the best use to be made of materials with respect to expense and effective appearance. Accompanying these hints I have some further drawings to show, particularly that class of photographer whose plans for

Fig. 3.—For a village or country photographer.

place of business are limited to the most modest expenditure. Simplicity and economy are not necessarily antagonistic, as I shall endeavour to convince my readers.

The shop-fronts, Fig. 1, intended to be executed in stone or brick (though the design might also be carried out in terra-cotta or faience), is, of course, by reason of its comparatively high cost, most suitable for a large and important establishment in the streets of a large city, and where a considerable amount of work, for the adequate display of which its principal window has been especially designed, was done. In order that large work might not swamp and overpower the smaller specimens, a separate window is provided for the latter while a wall-case on the left of the doorway would be very suitable for miniatures or other small pictures which need close examina-

tion for the proper appreciation of their merits. The woodwork might be of dark polished mahogany or rosewood, and the floor of doorway would be laid with Roman mosaic. Several different sets of window draperies should, of course, be provided.

Shop-front No. 2, of less cost, is essentially a design for woodwork, and would be preferably executed in oak, though in stained redwood, or in painted deal, it would, I think, prove very satisfactory. The symbolical design in the doorway would be carried out in granolithic.

The perspective sketch, No. 3, shows the treatment of a small bay window for a country or village photographer who does not produce much large work or require much space for the exhibition of his specimens, but who yet desires to have them in a

Fig. 4.—An ordinary shop front, converted.

pleasing and appropriate setting. It is a design that could be easily elaborated or enlarged to meet more ambitious requirements.

Fig. 4 shows how a very ordinary and commonplace front, such as is found in every town, may very easily, and at small expense, be converted into something more pleasing and artistic. The plain piers have been cased with quite simple woodwork and the upper portion treated with slightly rough white plaster, the cornice and necessary lettering completing the design, the window frame and doors having been left in their original form, and only painted to match the rest of the woodwork, which might very well be a very dark green, or brown.

DRINKWATER BUTT, F.R.P.S.

(To be continued.)

## THE PROFESSIONAL USE OF PRINTING PROCESSES.

From the introduction of the collodion process up to the time it was superseded by the gelatine plate—the early eighties—for some years after, albumenised paper reigned supreme as the printing process in professional photography. Non-printing, which in the seventies had been improved into a practical process—indeed, the process was the same as we have it to-day—gave it a shake. A good many professional photographers took up carbon, recognising that the results could be made of a similar character to albumenised paper prints, and equally beautiful, with the advantage that there was permanency to recommend them to the notice of their customers, and a higher price could therefore be charged. One after another, those who had attempted to introduce a new order of things were obliged to abandon their attempt,

not on account of any imperfection of the process, nor because the public did not appreciate the advantage, but simply because the constantly varying climatic conditions of this country made the working of the process uncertain, at any rate under the conditions that the average professional photographer conducted his business. The platinotype process for black tones was then also quite a practical one. Apart from certain commercial reasons which existed then, but which do not exist now, the cold tone and matt surface, the want of the kind of brilliancy people had been accustomed to in a photograph, combined in repelling popular favour, while the extra cost and the commercial difficulties referred to were perhaps among the reasons that professional photographers did not push the process as they might have done. So that the change in the

negative process did not immediately lead to a similar change in the printing process.

### The Bygone Album.

Those were the days when the album portrait was the photographer's daily bread. Cartes-de-visite were going out of fashion, the cabinet was getting popular, both especially designed to be kept in albums, and although other sizes were being pushed by the more advanced photographers, the panel and the boudoir, etc., the universal style of mounting was that of the carte-de-visite, a narrow margin at the top and sides, and a little wider one at the bottom bearing the photographer's name and address. Possibly some of the present generation of photographers, professional and amateur, may indulge in a scornful smile at the want of taste, artistic feeling, etc., of their predecessors who bound themselves by such a limitation; but, at least, there was a sound commercial reason for their methods. It was the family album that raised professional portraiture to an important industry. Mrs. Smith had her portrait taken, and distributed a dozen prints to a dozen people. A dozen family albums were enriched by Mrs. Smith's picture, and Mrs. Smith expected her own album to be added to in return; and as long as people were prepared to play this game professional photography prospered exceedingly. But games of this kind do not remain popular for ever. Sometimes they fade away after a brief season, never again to reappear; but this game has had a goodly run, and probably this article may be read by many in remote parts where fashion-changes are not quickly felt, and where the cabinet portrait in its original style is still the standard article.

### The Effect of Exhibitions.

It must be recognised that the album portrait almost compelled the use of a fairly highly glazed surface and a warm-toned print with considerable contrast, and that a platinotype print, however good it may be, does not look its best in an album. But the breaking away from the conventional style, it must be conceded, was primarily due to the rise of amateur photography. The amateur photographer usually practises on landscapes, and as there has never been the same conventional mounting of landscape photographs, he has followed his fancy in this respect, and looking upon his photograph as a picture, has endeavoured to display it to the best pictorial advantage. Photographic exhibitions have accustomed people to photographs mounted otherwise than in the old conventional style, and photographers have wisely followed the times, and have provided photographs mounted and got up as pictures. Hence the greater scope for the photographer in his choice of printing processes. If thereby photographers have lost the stimulating influence of the album, they have at least the consolation that their modern productions, if stuck up upon mantel-pieces, pianos, etc., as they frequently are, will soon soil and become unrepresentable, and thus leave room for more.

### Platinotype and Carbon.

Throughout the country it will be found that in those studios where fairly high prices are obtained, sepia platinotype is the process most frequently employed for the best work, a slightly lower price being charged for black platinotypes. Initially the material is expensive, but there is the compensating advantage that the process is free from a series of complicated operations, and the time occupied from the printing-frame to the completed print is short. Moreover, the print is an amenable one. Almost any amount of hand-work may be put upon it, or the air-brush may be employed without showing a trace of touching. Hand-work is necessarily expensive, but this facility permits the photographer whose prices enable him to spend time over each individual print to send out results finished in a way that would be impracticable in prints by any other process. The new

Japine paper affords a slight variation in both tone and surface, and is coming largely into use.

Carbon-printing is not, we believe, extensively used for small work. The firms who send out carbon prints, as a rule, make their results so like platinotype as not to be distinguishable at a glance, or choose bright tints unattainable easily by other methods. The process itself is not a difficult one, requires special arrangements, and is not easily carried on side by side with other photographic operations; moreover, as the whole process differs so entirely from other printing processes, assistants require special training, and there are not many of them available. For these reasons carbon prints are usually priced about the same as platinotype.

### The Bromide Process—Present and Future.

Regarding these two as the regal processes, at the other end of the scale we have bromide and gaslight papers. It would probably be found on investigation that the amount of these papers used far exceeds that of all other papers together. The area of bromide paper turned into enlargements in this country probably runs into square miles weekly, but apart from enlargements an enormous quantity is used by the countless "stick back" photographers who have sprung up during the past few years. In medium-class businesses, where the price for platinum cannot be obtained, a fair substitute is found in these papers. A good print on gaslight from a suitable negative leaves little to be desired. The manipulation is easy and speedy, the paper is cheap, and there is no reason that fairly high prices should not be obtained for carefully-made prints, tastefully mounted from good negatives. Toning processes are not so frequently employed as they might be. The sulphide method has been made sufficiently certain in the hands of a reasonably skilful operator to be commercially practical, and the results are very pleasing, often indistinguishable from carbon printing without careful examination; but the fact that there is an extra chemical process, and one requiring a certain amount of care, fullness and precision to obtain even results, seems to act as a deterrent. For the rapid production of proofs for reproduction glossy bromide or gaslight is constantly employed, and prints may be made in this way of a quality eminently adapted for the purpose. The postcard publishers use toned glossy bromide or gaslight extensively, and many of the postcard portraits of actors, actresses, etc., issued in this way are most beautiful prints. The tones—or, rather, the tone—obtained, from one of the most noticeable features of the work is its equality of tone, is rich and pleasing, and as prints they bear comparison favourably with the best by any other process producing glossy prints. For this work the hot hypo-alum bath is exclusively employed; but a few photographers, during the dark period of the past winter, have sent out sulphide-toned prints instead of P.O.P., and the results are indistinguishable, at any rate to the uninitiated. Manufacturers have recently been pushing semi-matt papers of these kinds under various trade names, and have also graded their papers according to the various qualities of negatives they are suited for, so that the applicability of the process is being vastly extended. It is hardly too wild a prophecy to make that in time developed prints, toned or otherwise, will supersede printed-out prints for ordinary purposes.

### Printing-out-Papers.

The process that has given the knock-down blow to albumenised paper is gelatino-chloride, or P.O.P. Probably it requires greater skill to make a perfect print on P.O.P. than on albumenised paper, but that it can be purchased ready prepared at a uniform in quality, and that it does not deteriorate with moderate keeping, are among the factors that have led to its adoption. A few years ago a show-case of P.O.P. prints was frequently indistinguishable even from the other side of the road by its aggressive blue and plum tones; but better acquaintance

part of photographers with the treatment of the paper, perhaps still more the improvements made by the manufacturers in this quality, and in adapting it to various toning methods, have led to a great improvement in the average results obtained. Shocking examples are still to be seen; but photographers always were, and always will be, capable of producing bad results, however perfect the material employed. P., then, has practically superseded albumen, and where a few years ago when no specified kind of prints was ordered, men's prints would be supplied as a matter of course. Now we would expect to receive P.O.P. prints.

Matt or semi-matt P.O.P. does not appear to have come into favour with photographers, probably on account of the fact that, except with negatives perfect in gradation, and precisely the scale to suit the paper, the shadows are apt to be heavy and wanting in depth, and that when an order has been taken for these prints, and the negative does not turn out just the correct thing, the results are not as good as they might have been with a paper possessing more latitude, if we use the expression in this connection. For matt or semi-matt prints having similar characteristics to albumen prints, ferro-chloride, or, as it is popularly known, C.C. paper, is much in vogue. Many of the best establishments only push cyanotype, carbon, and C.C. The paper may be simply toned, the more fashionable method is the employment of two separate toning processes, platinum being the toning agent in one of the processes and gold in the other. In this way very beautiful effects are obtained, often of the same nature as those

obtained in the printing of an etching by the judicious leaving of a smear of ink on the face of the plate at the discretion of a copper-plate printer of artistic as well as technical skill. Reasonable prices are obtained for C.C. prints, and the work deserves to be well paid for, as it requires considerable technical ability and much precision on the part of the printer. The C.C. papers furnished by the various manufacturers differ a good deal in the methods of treatment best adapted to each individually, and it therefore follows that the particular treatment that will produce the best results with one brand of paper will not necessarily produce the best results with another brand. Probably a great many complaints of difficulties arise from want of recognition of this fact; but undoubtedly slap-dash methods are more fatal in this process than in most, and faults are more difficult to trace to their cause.

Self-toning varieties of both C.C. and P.O.P. papers are sometimes used, and the results are obtained with the minimum of trouble. The results are similar to those obtained by simple gold toning, but may be modified by an extra process of platinum toning; but so used, these papers hardly pay for their extra expense.

In reviewing the various printing processes in ordinary use throughout the country, the faults that are common to any attempt at generalisation must necessarily occur. In different parts, photography, like other things, is in different stages of advancement, and what may be accurate as a generalisation may be quite wide of the mark with regard to a particular district.

ALEXANDER MACKIE.

## PERMANENT PHOTOGRAPHS—INSTRUCTIONS IN FOUR MODERN PROCESSES.

During the last year or so the photographic world has been enriched by the introduction of four methods of making permanent prints, the Oil, Bromoil, Ozobrome, and Carbograph processes. All four achieved a large measure of popularity in very short time after their introduction, and to-day they all rank as important processes: therefore a brief description of each one from the pen of Mr. C. Welborne Piper, himself the discoverer of the Bromoil process, may be of interest to the general readers of "The British Journal of Photography."—Ems. "B.J.]"

### The Oil Process.

It was first brought by Mr. Rawlins to a workable state of perfection, though not exactly a new invention. Practically, it is a variant of the collotype process, the pigment being applied with a brush instead of a roller.

The procedure is very simple to describe, though considerable experience is required to perfect the final result. The process is as follows:—

Latino-coated paper—carbon transfer paper is very generally used—is sensitised by immersion in a 5 per cent. solution of potassium bichromate for one minute. It is then dried, and a dry contact print from a negative is made upon it by light. A faint brown image is thus produced, and when all is visible the print is taken from the frame and washed for 10 to 30 minutes. This washing removes the yellow bichromate stain, and at the same time swells the gelatine in the unexposed parts of the film. The exposed image is, however, non-soluble, and if the washed print is laid on a thick pad of wetting-paper, and superficially dried by dabbing with a soft handkerchief, the image speedily becomes quite dry and capable of receiving a sticky oil pigment, though the rest of the gelatine remains so moist that the same pigment will not adhere to it.

The pigment commonly used is specially prepared for the purpose, but lithographic ink can be employed, and is regularly used by some workers. A somewhat stiff, tacky pigment is serviceable, as a thin one tends to give rather too soft an image. The skilled worker uses pigments of various consisten-

cies, according to the effect he desires to produce. The pigment is applied by dabbing with a thick, short, flat-ended brush. The soft-haired brushes known as china-painters' dabbers are in most general use, but special brushes are also made in both soft and stiff hair. A very little pigment is carefully spread out on a palette with a knife, and the brush is lightly charged from this palette. By repeated dabbing on the print the detail is gradually brought out until the required density is reached. An excess of pigment can be removed by dabbing with a dry or nearly dry brush, or by a peculiar brush action styled very descriptively as "hopping." Every worker has his own methods of pigmenting, and the beginner very soon develops methods of his own. The peculiar advantage of the process is, of course, the facility with which the tone values can be controlled or modified by the worker. He can apply the pigment or leave it out where he pleases, and he can control the depth of each tone and introduce softness or emphasis just as he pleases. This, of course, places a great power of control over the result in the hands of the skilled worker who knows what to do, though at the same time it offers many traps for the unwary. Indeed, no other process offers such opportunities to the expert, and none is so certain to reveal the incapacity of the unskilled.

### Ozobrome.

This is a modified carbon process, due to Mr. J. Manly. It is, in brief, a method of producing carbon prints direct from bromide enlargements without any process of printing by light, and it has the very important advantage that a number of car-

bons can be prepared from the same bromide. The process can be very simply described as follows:—

A special "Ozobrome" or "pigmenting" solution is prepared and sold by the inventor, and one part of this solution is mixed with four parts of water. The bromide print is soaked in water, and at the same time a sheet of "pigment plaster," which is a slightly modified form of carbon tissue, is also soaked for half a minute. The tissue is then removed from the water and soaked for two minutes in the prepared "Ozobrome" bath, and then the tissue and the bromide print are squeezed into contact and left under slight pressure for 15 to 20 minutes. After this there are two courses open to the worker. He may proceed exactly as in single transfer carbon printing, allowing the bromide print to take the place of the transfer paper. That is to say, the two papers together can be placed in hot water at a temperature of 104 to 106 deg. F., and, after a short immersion, can be pulled asunder, when the pigment will separate from its original support and remain upon the bromide print. Development then proceeds exactly as in the carbon process, the difference being that the final pigment image is superimposed upon the original bromide image. This silver image was, however, bleached by the Ozobrome solution, and is practically colourless. It may be left like this, in which case it will slightly darken its course of time by the action of light, or it may be at once redeveloped to blackness, the effect of which is an intensification of the whole image and a darkening of its colour. Or, again, the bleached silver image can be completely removed by a hypo bath, when the pigment image alone will remain.

The above is known as Method 1 of the Ozobrome Process, and while it has certain advantages, of course, the bromide print cannot be used over again. Method 2 is as follows:—

Instead of placing the squeezed prints in hot water, they are immersed in cold, and at once separated. In this case the pigment adheres to its original support, and the bleached bromide print is left quite free from pigment. The tissue or pigment plaster is now exactly in the condition of an exposed carbon print, and is treated in the same way. It is squeezed to a piece of soaked transfer paper, left under pressure for 15 to 20 seconds, and then developed in hot water in the usual way. Meanwhile the bleached bromide print is washed free from traces of the Ozobrome bath, redeveloped with any suitable developer, and washed and dried. After this treatment it can be used over again for the production of another carbon print, if desired, or kept as it is. It is in no way damaged by the treatment, and it will be found to be slightly intensified, and probably improved in colour and richness.

### Bromoil.

This process was worked out by myself for precisely the same reason that induced Mr. Manly to work out the Ozobrome process. The oil and carbon processes both depend on the hardening action of light on bichromated gelatine. Daylight exposures are necessary in both cases, and if large prints are required from a small original negative the production of an enlarged negative is essential. The Ozobrome process was designed to dispense with daylight printing and the making of enlarged negatives, and as soon as the Oil process was introduced it became evident that a similar simplification was very desirable. It is quite possible to produce an image in bichromated gelatine that will take the oil pigment by applying the Ozobrome method. That is to say, we can substitute a sheet of gelatinized paper for the carbon tissue, soak it in Ozobrome solution, and squeeze it to the bromide print. After about twenty minutes the two can be separated, as in method No. 2 of the Ozobrome process, and, after washing, the image formed in the gelatine can be pigmented. This is, however, a process that does not often yield good results. The image produced does not seem tough enough to stand the somewhat

rough treatment of pigmenting, and as a result detail is readily lost in the high-lights and half-tones. Moreover, the final result is a reversed image. These disadvantages make it very desirable to find some method of bringing the bromide print itself into a condition for pigmenting, and the Bromoil process is the result. The Ozobrome solution is still used but in a modified form.

The bromide print is first soaked in water until limp, is then bleached in the following solution:—

Ozobrome stock solution .....	4 parts.
10 per cent. potash alum .....	4 parts.
10 per cent. citric acid .....	1 part.
Water to make .....	20 parts.

Bleaching takes less than a minute, and when completed the print is very briefly rinsed and immersed in 5 per cent. sulphuric acid for two minutes. After this it is rinsed again and is then put into a fixing bath composed as follows:—

Hypo .....	2 ozs.
Soda sulphite .....	½ oz.
Water to .....	20 ozs.

After two or three minutes' fixing it is washed in three or four changes of water, and is then ready for pigmenting in the same way as an oil print. As an alternative, however, it may be dried, and it can be brought into good condition for pigmenting at any future time by simply soaking in water for about ten to twenty minutes.

The pigmenting is conducted in just the same fashion as oil printing, but there is a very marked difference in the way in which the print takes the pigment. The Bromoil print takes the pigment more readily, and can be finished in very much less time. An oil print can easily be pigmented in such a way as to hide all detail, whereas the Bromoil print reveals detail at almost the first touch of the brush. The latter is therefore the easiest process if it is wished to preserve as much as possible of the photographic character of the drawing, while tones can be modified or emphasised just as readily as in oil printing.

In this process the water and all the baths used should be at a temperature of about 65 deg. F. If less, the process may fail, while if the temperature is too high the gelatine becomes soft and rotten. The bleaching and acid baths, also, should not be overworked. Ten ounces of each should not be used for more than six 10 by 8 prints, and even this number is too great if the rinsing after the bleaching bath is omitted. If only one print is treated, there is no necessity to rinse. The print can go straight from the bleacher into the acid bath, and from that into the fixer, but if several prints are to be treated it is necessary to rinse between the baths, to save the last from rapid exhaustion. As a rule, it is advisable to have a spare print or so of the subject handy. One can be used for experimental pigmenting to test the effects obtainable, and a second one can be used for making the finished print, which is all the better if pigmented boldly, and not worked up too long or submitted to alterations. As the preparation of a print for pigmenting can easily be completed in ten minutes it is as well to prepare each one as wanted. Nothing is gained in point of time by preparing several and allowing them to dry, and they must not in any case be allowed to remain in the water too long before pigmenting, otherwise the image may soften. A freshly prepared print should be laid on a board for pigmenting within twenty minutes of the beginning of the operations, otherwise difficulties may be met with.

### The Carbograph Process.

This is another method of producing carbon enlargements, it differs from the Ozobrome process in that the enlargement is produced direct from the original small negative. The theory of the process is much the same as that of Ozobrome,

instead of obtaining the carbon print by squeegeeing carbon sue on to a bromide print, the bromide and carbon films are incorporated into one emulsion, with which the "Carbograph" per is coated. The bromide enlargement is produced by the ordinary method, but within the carbon film. On treating the result with a bichromate bath or sensitiser, a hardened carbon image coincident with the bromide image is formed, and the result is then treated just like an exposed carbon print. The following is the exact procedure. Carbograph is put on the market by the Rotary Company, and the speed of the emulsion is described in terms of that of Rotograph bromide paper, which is about 25 Watkins. First arrange apparatus set in the same way as for producing ordinary enlargements, and ascertain the correct exposure for a bromide enlargement developed with the iron developer given later, and note also the time of development that gives the best result. The correct exposure for a Carbograph print is then determined by multiplying the time already found by one of the following factors, which vary according to the colour of the tissue selected:—

Warm sepia .....	5	Engraving black .....	9
Light green .....	7	Photo-brown .....	10
Cold sepia .....	8	Red chalk .....	10

The time of development for the Carbograph will be the same for the bromide print, which will generally be found to vary from five to seven minutes. The developer used is either special iron citrate developer sold for the purpose, or the following:—

I. Potassium oxalate .....	6½ ozs.
Hot distilled water to .....	20 ozs.
II. Ferrous sulphate .....	1½ ozs.
Citric acid .....	48 grs.
Distilled water to .....	5 ozs.

Add 1 oz. of No 2 to 5 ozs. of No. 1, and to the mixture add drops of 10 per cent. potassium bromide. When the time of development is completed, immerse print in 1 per cent. acetic acid for one minute, then wash in three or four changes

of water and immerse for three minutes in a sufficient quantity of the following sensitiser:—

Potassium bichromate .....	1 oz.
Water .....	25 ozs.
Potash alum (10 per cent. solution) .....	½ oz.

The alum should only be added just before use, and the bath should be thrown away after use. The dish must be kept rocking during the sensitising operation. When this is finished the print is washed in three or four changes, squeegeed to transfer paper, left under slight pressure for ten to fifteen minutes, and then treated just as an ordinary carbon print. That is to say, it is developed in hot water at a temperature of 105 deg. F. When developed, it is treated with a 20 per cent. plain hypo bath, to remove any silver bromide left, is washed, hardened in 1 per cent. alum, rinsed, and dried. The result then contains the silver image as well as the carbon, and the former can be removed, if desired, with a strong Farmer's reducer.

The process may seem complicated from the description, but as a matter of fact it is a very easy one to work. If the exposure and first development are correctly adjusted in the way described, the rest of the proceedings work almost automatically. The final reduction must be adopted with caution, as it tends to reduce contrast. The three most rapid papers seldom want it, as they naturally give soft results. The other three give strong contrast, and are often improved by reduction. In the process the colour of the photo-brown is altered to a certain extent, while the red chalk colour is only obtained in the case of the last paper when reduction is complete. The unreddened print is a brownish red.

The Bromoil, Ozobrome, and Carbograph processes all have considerable scientific interest, as they depend on a somewhat mysterious hardening process (of the gelatine) that is not yet properly understood, though in all probability it is destined to play an important part in other new photographic processes. The three mentioned are therefore very attractive to the experimenter, who soon realises that the same mysterious action has many possibilities.

C. WELBORNE PIPER.

## CONVERSATIONS ON COPYRIGHT.

**COPYRIGHT.** The sole and exclusive right of copying, engraving, reproducing, and multiplying any photograph, and the negative thereof, by any means and of any size.—[Extract from the Copyright (Works of Art) Act (1862).]

Taking this explicit definition of copyright from the Act, the present series of conversations will aim to convey by means of examples and simple dialogue the way in which the act affects the photographer: I., as regards ownership of the copyright; II., as regards registration; III., as regards sale and part sale of copyright; IV., as regards infringement of copyright; and V., as regards copyright in foreign countries.

### I.

#### THE OWNERSHIP OF COPYRIGHT.

**Q.** : As a photographer, I assume that any photographs I make are my copyright?

**A.** : Only in certain circumstances.

**Q.** : Can we define these circumstances?

**A.** : Certainly; the Act is most clear on the subject. If you take a photograph for your own use, the copyright is yours. If you take it for someone else, who agrees to pay you, the copyright belongs to the person who employs you.

**Q.** : Do I understand you, this question of payment decides to with whom the copyright rests?

**A.** : It's not exactly that. The Act says that when taken

We will ask the reader to assume that he is the querist (Q.) and that the answers (A.) are given to him (as they are) by one who has had cause to digest every sentence of the Copyright Act, and of the judgments in the courts, and has, moreover, for years past rarely passed a day without having some incident of a photographer's business in which copyright was concerned brought before him for his advice. Having thus cleared the ground and established, it is hoped, a mutually friendly understanding between questioner and informant, we may proceed to the first section of the subject—the ownership of copyright as it affects the photographer.

"for or on behalf of another person for a good and valuable consideration, the copyright is the property of the person for whom or on whose behalf it was taken."

**Q.** : Is there any difference? A person pays me to take a photograph; the copyright is not mine, but his.

**A.** : Certainly; but even if he fails to pay you—if, like Mr. Skimpole, he pays you only "in his expansive intentions"—the copyright is still his, not yours.

**Q.** : Is this what you call receiving "good and valuable consideration"?

**A.** : The Act refers to the work as being done "for a good or

valuable consideration." It leaves you to see that you get it. That is, it does not differentiate between the man who pays you for taking the photograph and the man who owes you; both stand on the same footing as regards ownership of the copyright.

Q.: So that if I photograph a sitter from whom I cannot get the money, I am still prevented from recouping myself by using the negative or the prints for any other purpose?

A.: Unless you have the sitter's permission, you are. It amounts to this: If you are in a position to sue for payment for the taking, you can't (for that very reason) have any ownership in the copyright. That is a convenient test to apply if you have doubts as to your position. You must realise you can't have your cake and eat it; payment for the work or copyright in the prints: one or the other, but not both.

Q.: I have another case in which I am in doubt. A customer came to my studio and asked to be photographed, and for proof to be submitted before he will give an order or pay anything. This I have done, but have heard nothing of him.

A.: The transaction is unbusinesslike, but his visit is certainly an implied promise to pay if the proofs are satisfactory. In the event of their not being satisfactory, presumably under copyright law, the copyright would be yours, you having received no valuable consideration. But the aspects of such a case under common law might involve some nice points.

Q.: All this applies to a sitter coming to a studio or to a photographer dealing with customers. But suppose I am an operator or assistant?

A.: You are none the less receiving "good and valuable consideration" for what you do. You are paid wages, or salary.

Q.: Suppose I can't get the money?

A.: The same applies. Your employer is liable to pay, and it is open to you to sue him. In these circumstances, whatever photographs you may take in his studio or when travelling for him are his copyright.

Q.: Must this "good and valuable" consideration be money?

A.: It need not be. The acceptance of articles of value, or of board and lodging, may be agreed upon as "valuable consideration." There is, in fact, one case on record in which the granting of permission to photograph certain premises was judged to be "valuable consideration" to the photographer, because it gave him the opportunity to sell numerous copies of the photograph thus taken.

Q.: I suppose the copyright becomes void on the death of the person who commissioned the photographer. For example, I was recently commissioned to take some photographs of a monastery. The abbot paid me, but as he is now dead, I suppose I am at liberty to issue copies of the photographs, say, as postcards?

A.: That you certainly are not. Copyright in all cases lasts for the life of the *author* and for seven years after his death.

Q.: Does this apply to a photographer working for himself as well as to one employed to take negatives?

A.: It applies without exception in all cases. But if the negative be sold without proper "assignment" of the copyright, the copyright becomes altogether lost.

Q.: There we seem to have a point which bears on the professional. If I buy a business, it is therefore necessary, is it not, to see that the copyrights are transferred to me simultaneously with the negatives?

A.: Certainly it is. A list of the copyright subjects should be made, and the copyrights assigned in writing to the purchaser. This document should be stamped with a sixpenny stamp.

Q.: Must I, as the new proprietor, re-register each separate copyright?

A.: That is a point which I can best deal with in our next "conversation," viz., that on "Registration."

Q.: At any rate, here is a case which I should like settled. I go to a sale and purchase a number of negatives (the original owner having died). Another photographer, B., at the same time purchases in another lot the certificates of registration of some of my new negatives. Can he stop me from printing the latter as postcards or in other ways? He has said he can.

A.: He cannot. The sale of the negatives without proper transfer of the copyright has caused the destruction of the latter. Anyone is at liberty to print from the negatives, and—unfortunately for you—to copy the prints.

Q.: We were speaking just now of the duration of copyright—of its lasting for the life of the author and seven years after his death. In the case of a portrait business, who is the "author" of the photograph, the proprietor of the studio or the paid operator?

A.: It has been decided that the "author" is the person who is, as near as he can be, the cause of the picture which is produced: that is, the person who superintended the arrangement and placed, say, the figures in a group in position.

Q.: How about an operator who, in the absence of the proprietor, simply carries out certain instructions given him by the latter?

A.: Legally he is the "author," although, had the proprietor been present and personally given the directions, it is probable that he would be regarded as the "author," even though he did not actually raise a finger in manual labour.

Q.: I understand, then, that the duration of copyright is fixed usually by the life of the operator. Do you mean to say that in the case of a view-publishing business a copyright expires seven years after the death of the operator who took the negative?

A.: It does.

Q.: Does not this confer great licence on persons who would reproduce photographs without paying the proper fee?

A.: One might assume that it would, but there is no record of a case in which action for infringement has been defended by alleging the lapse of the copyright by the death of the author. Usually it is difficult to discover what has become of an operator.

Q.: Perhaps you can tell me now what happens to a copyright of a sitter's photograph on the death of the sitter? I assume that the author is still alive.

A.: Copyright can be willed to any person, or passed to the heirs, executors, or assigns, like any other property. Whether it is necessary for this purpose that the copyright should be registered is a debatable point, and there is no decision in the courts upon it. In any event, all that can happen is that the copyright may be destroyed.

*The remainder of the conversation must be postponed until next week.*

FEATURES OF THE "B.J."—The regular weekly issue of THE BRITISH JOURNAL OF PHOTOGRAPHY includes:—"Ex Cathedra" (notes on current topics); contributed articles by British writers and translations of the best matter in the Continental journals; "Patent News" (abstracts of British Photographic inventions and a file of applications for patents); "Analecta" (extracts from other English

photographic papers); Reviews of New Books, Materials, and Apparatus; Commercial and Legal Intelligence; News Items; Letters to the Editor from readers; and "Answers to Correspondents." A very complete Annual Index is a great feature of the "B.J.," the volumes of which thus form storehouses of readily accessible information.

## THE WORK OF S. ELWIN NEAME IN DECORATIVE PHOTOGRAPHY.

in advertisement-making as it is in Limerick competitions any are called but few are chosen. The reason for this is that few can command the necessary taste and fitness. Mr. Elwin Neame is one with gifts in this direction should make him more than ordinarily successful. Though but young, Mr. Neame has had quite an experience in photographing professional beauties, and he could probably

photograph by]

S. ELWIN NEAME.

[E. O. Hoppe.

on his fingers the stars of the musical stage whose portraits has not committed to the photographic plate. Now he has turned himself to a bye-way of South Kensington—Margravine Road, Baron's Court—there to prosecute a branch of art which he has made peculiarly his own, and is applying with a persistence which should have its commercial reward. Of us have admired Mr. Neame's work in the exhibitions on reproduction, also all unacknowledged on the window of the plate and paper manufacturer to whom the trinity of grace, feminine attractiveness, and good photography, which produce of the Neame studio; has been quick in appeal. Though your amateur buyer of Somebody's P.O.P. may not notice it, the show-card which finally caused the purchase owed its languorous beauty of flowing lines, flowing hair, flowing tresses, and flowing limbs to Mr. Neame's patience and long time.

One knows better what financial advantage rests in having a pretty face at command as well as the taste to pose it. A figure is of less value in Mr. Neame's hands, for he does flow more than a bewitching throat or a perfectly tanning shoulder of it to be seen. Therein comes his fine-artful-

ness. His particular model may have a bewitching figure too, but he takes care not to give us any "definite data" on that point, and as a consequence we give her the benefit of the doubt in our imagination, and are as charmed with her *tout ensemble* as if we had a complete Puyo before us. This suggestion is, in reality, of more worth upon a show-card than a fuller and more pictorial subject would be, which might engross a buyer's attention too deeply. Mr. Neame's faces and hazy draperies attract, partly by what they do not offer, and, having attracted, they do not hold too exclusively. What could a manufacturer want more? Hitherto little of Mr. Neame's work has been seen in advertisements reproduced in half-tone, though that, one would think, must be an obvious application of it. In reproducing one study which we brought away from Mr. Neame's studio we have taken the unpardonable liberty of supplying the lady with a pair of feet which she could comfortably swallow, and of surmounting her with a panel on which, in an advertisement, would appear the name of So-and-So's furs or hats. Mr. Neame will disown this artificial silhouette-like figure; but we reproduce

WITH APOLOGIES TO MR. NEAME.

Liberties have been taken with the photograph to show the adaptation of Mr. Neame's work to newspaper advertising.

the photograph to show that his work is not all among the damsels of a gauzy Utopia.

But whether Mr. Neame keeps on his present profitable lines, or whether he embarks upon other ways, he is pretty sure to

A woman reclining in white and drapery.

A photographic design by S. Elwin Neame for a heading to a magazine article.

duce the attractive thing. Perhaps the ornamental arrangement shown in the fourth example will develop into something suitable. In that design a portion is pierced to admit letter. This plan requires more care in printing than is always obtainable, otherwise the cut edges reveal a decidedly unpleasant mess and hardness of edge. But on these points the wishes

of clients must be deferred to. Mr. Neame, as we have said, has youth and enthusiasm on his side, and a great asset is the high excellence of his work in negative-making and printing. With such aids to his originality, it must surely happen that his determination to specialise in decorative photography will not fail of its reward.

## SOME BUSINESS METHODS IN CANADA.

CONSIDERATIONS of fraternity have induced me to record, for the benefit of the craft in the Old Country, some of the conditions of the business which obtain in Canada, which, be it said, are greatly inspired by the go-ahead methods of our cousins over the border.

### The "Two Cabinets for 50 Cents" Dodge.

A reasonable and satisfactory amplification of the free cabinet system is that which offers to intending patrons two cabinet photographs for 50 cents, payable to the agent or canvasser. In this system the studio which puts out the coupon "stands the racket" of two cabinets, and plumps on its business acumen to increase the number when holders of coupons turn up for a sitting. The 50 cents, of course, goes to the agent, who draws no salary, and is entirely dependent therefore on his own skill and resource and the excellence of his specimens for his living.

The strong point here is the fact that the 50 cents paid by the customer guarantees in some part his intention to pay the studio a further amount—about 80 per cent. of the coupons are redeemed. The principle is sound, because it implies that people who want photographs will pay for them, if only as much or as little as 50 cents. As far as the studio is concerned, perhaps even a smaller coin would serve well, or better, on the assumption that more people would buy for 25 cents than at 50 cents. But there is a limit to the number of houses an agent can visit in a day. He must be paid for his services, and the larger the amount paid by the customer the more the guarantee that he will not change his mind.

### At the Studio—"Floating Sepias."

Naturally, it frequently happens that, however good the photograph, only the two pictures contracted for are completed. "But," says the proprietor of one such studio, "such cases are not more frequent than we can help, for customers never leave my reception room until we have shown them all we have to show. If we believe in our excuses as to the limited time at their disposal, we declare that we cannot do them justice in so short a period, and will they call again—by appointment. If we disbelieve them we remark, 'You see, I am a lam' (or Sir, as the case may be), 'we do this for advertisement, unless we get our advertisement we cannot afford to give away photographs. We are not philanthropists, neither are we here for our health; on the contrary, personally speaking, I am here for the sake of my health, and the least you can do, now that you have got our elevator, is to spare a few moments inspecting the various photographs we have to advertise. Those beautiful 'Floating Sepias!' you see they are attached to the card merely along the top edge, that's why they float, etc. etc.'"

### The Endless Chain Method.

The free enlargement, with three or half a dozen cabinets, is the outdone by another photographer of my acquaintance who, on return for six introductions of clients for a dozen cabinets at a price, returns the price of the photographs originally supplied by the introducer. Thus, on the completion of an order, six coupons are enclosed in the package, each bearing the name, number, and address of the patron. These are distributed among the first sitters' cards, and as they are presented at the studio they are filed and the rewards noted in the Studio Register, or a separate book kept for the purpose against the name they bear, as having been presented and completed. The whole half-dozen booked, a cheque is sent to the patron through whose good offices they came to be presented. But the weak part of this scheme is the fact that people who want photographs will pay for them. Thus it comes about that more than half the patrons do not, or only partially, use the coupons. The rest do, and business certainly accrues to the photographer perhaps otherwise would go somewhere else.

Incidentally, I may mention that the coupons are all perforated with a hole about  $\frac{1}{4}$  in. in diameter, with the legend beneath it, "Look through this hole at your pictures, and the figures will be seen in relief," which, quite apart from the matter of fact, is designed to give an intrinsic, if temporary, interest in the card for other purposes than the business to which it is to be applied. Of course, every customer who turns up gets another six cards to distribute, which makes for the "endless chain."

### The Toilet Mirror Game.

An American firm of mirror and toilet manufacturers also employs a large and accredited posse of canvassers for their products, which they work in this fashion. A handful of these men descends upon a town under a leader, who visits the local photographers with the following proposition:—After inquiring as to business generally, the prices obtained, and satisfying himself as to what success is likely to be reached by "boosting" the studio's work, the agent produces a "grip" (Americanese for hand-bag), containing samples of a neat circular mirror about five inches in diameter, on the reverse side of which is another mirror, silvered so as to leave a circle opening in the centre of clear glass. By a clever arrangement of a screw at the base of the handle the mirror becomes removable, and the photograph is inserted between the two glasses. This is the extra photograph given away in the mirror.

Then the agent explains how he will enable the studio also to give away the mirror away with a certain number of photographs at a fixed price, said price to cover the agent's canvassing fee, plus the price of the mirror, plus the least the studio will turn out half a dozen cartes-de-visite for, the total sum varying with different localities, according to the ruling prices. A similar mirror, brush, and comb, "all in case complete," are dealt with in similar fashion and, of course, at an advanced price, these to be given away with one dozen cabinets. It is fair to say that the mirror has all the appearance of a \$5 article.

The gang of accomplished talkers "stays by" the town until they have sold the uttermost coupon, the takings per man often averaging \$50 or \$60 per diem. This speaks as well for "proposition," as for their trained and, it must be admitted, often unscrupulous, solicitation. The business is not only confined to only one photographer in each town, but also to the photographic fraternity, to the exclusion of any store-holder who might desire to handle the same goods retail. And the applications of such are many. The whole corps numbers, I believe, forty canvassers, and the States and Canada have been, and are being, worked systematically. It is estimated that they will not get through with the Americans in a lifetime, so the prosperity of the firm is assured. It is, however, to be noted that, although the bait is changed once every three or four years, the same tactics are repeated, which affords ample proof, if, indeed, any of the sort were needed, that the business side of the "proposition" is sound and "live."

The "spiel" also is one which, owing to its great success as a money-getter, carries with it an implied threat of temporary comparative extinction in a small town for those of the fraternity who work at a moderate price. It certainly is a paying game for the mirror firm and the one photographer, who continues to be the sole local agent for this class of goods long after the cream is off the milk and there is any skim left.

I will only add that photographers who may have coupons in the field already, and who are not among the chosen ones, do not relish the presence of these voluble gentry in their locality, as they have, I believe, a practice of buying up from owners any existing coupons not their own they may happen upon. It is true that the agent by

so doing drops his 50 cents on the collection, but there is a gain to the firm of an extra chance of selling one more mirror to the photographer when that coupon is presented at the studio.

I am not here concerned with the business morality of such a procedure; I have the honour to record the fact for what it is worth.

"B.J."-ITE IN THE NORTH-WEST.

#### A NEW METHOD OF PRINTING—WITHOUT LIGHT—FROM NEGATIVES.

##### THE DONISTHORPE PROCESS.

In our issue of January 10 last we published the patent of Mr. F. W. Donisthorpe for treating a negative in such a way that the parts exposed to light—e.g., the sky—are made unsaturable by a dye solution, whilst unexposed parts remain easily saturated, the intermediate portions being saturable in proportion to their transparency—that is to say, a negative thus treated and dyed up yields to a moist sheet of gelatine-coated paper, squeezed in contact with it, a positive image composed of the dye. The above is the essential part of the Donisthorpe process of photography and by those familiar with colour printing processes will be seen to be a simplification of the pinatype process, the original negative being converted directly into a pinatype print plate. The solutions mentioned in the patent as capable of effecting this remarkable change in the negative include a mixture of vanadium chloride, potass ferricyanide, ferric chloride and oxalate, and oxalic acid and glycerine.

The Donisthorpe process thus consists in treating a negative in this way, dyeing it, and taking off prints by contact only on moist sheets of gelatine-coated paper. Our own trials some months ago with an experimental solution Mr. Donisthorpe sent us showed us that the process was workable, and we have therefore been interested in seeing, within a few hours of this issue going to press, a number of prints by the process of remarkably good quality, and resembling, some of them, P.O.P. prints so closely as to very well pass for them. The method is applicable to lantern slides and to printing from enlarged paper negatives. Moreover, it is proposed by the Donisthorpe Patents Company (at whose offices, 5, Southampton Street, Strand, London, W.C., we learnt these later details of the process) to issue a roll-film coated, not on a transparent support, such as celluloid, but on black paper, transparency of the negative not being needed for the Donisthorpe process. Advantage can thus be taken of the black paper support to obtain a perfectly non-halation flexible film, the negatives taken on which can be printed from as above described. We shall refer to the practical working of the process in a later issue.

#### THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION. ANNUAL REPORT.

THE following is the text of the annual report of the Committee presented at the annual meeting reported in our last issue:—

During the past year there have been seventy-five admissions to membership; this compares with seventy-seven last year and fifty-three the year before. This accession would be quite satisfactory were it a net increase of membership, but unfortunately on the other side there have been twenty-three losses through death or resignation, and through members having given up business or removed leaving no address, and fifty-two members have failed to pay their subscriptions for two years after eight applications.

The Workmen's Compensation Act having come into force on July 1, the Committee made arrangements with the Fine Art and General Insurance Company for the insurance of members' liabilities under the Act at a considerable reduction from the tariff rate of premium. Care was taken that the policy issued by the company was so drafted as to indemnify the insurer against every possible risk, and leave no ground for challenge, except for deliberate misrepresentation. The number of policies issued to members so far has been 108. That so few members have availed themselves of the arrangement shows probably that the majority have not yet realised that the risk of having to pay compensation is a real one, and one that it is quite as necessary to meet by insurance as the risk of fire.

The Committee have not relaxed their energies in fighting free-portrait swindlers, and others carrying on canvassing businesses of a more or less fraudulent nature. Through the instrumentality of Mr. H.

Comley, of Stroud, county-court summonses were served on the Glen Fine Art Co., of Manchester, on behalf of a number of persons that neighbourhood, who complained that having parted with photographs on the pretence that enlargements were to be made for them free, were unable to obtain return of their photographs. The claim was for damages for the retention of the photographs. The defendant company paid the damages claimed and costs, rather than appear in court. At Pocklington, Yorks, at the instance of our member, Mr. F. Slights, the Committee instructed a solicitor to defend two summonses issued by the King Edward Fine Art Enlarging Company, to recover payment for frames for enlargements that were represented to be made free. The result was verdict with costs for our side.

A letter calling attention to the fraudulent nature of the offer of free enlargements and the inadvisability of dealing with canvassers rather than the established photographers of the neighbourhood, signed by the Hon. Secretary, and intimating that the Association is willing to assist those who have been swindled, has been inserted in a large number of provincial papers (it was through this letter that the Stroud case came to the notice of the Association), and many instances country members have been instructed how to deal with cases that have occurred.

The sub-committee appointed to deal with the new Copyright Bill have held several conferences with the Committee of the Artistic Copyright Society, who are promoting the Bill. It has been by the threat of the strenuous opposition of our Association as a whole, and of each individual member of it, that any concession from the Bill as drafted has been obtained. If that had passed into law, it would have made the protection of photographers' copyright practically impossible in most cases; but in the agreed modification, though the sub-committee have not obtained all they fought for, the conditions have been made reasonably easy to comply with. The sub-committee recognised from the first that on any alteration of the law of copyright it would be impossible to maintain the privileges which photographers have hitherto enjoyed.

At the invitation of the Editor of the "British Journal of Photography," the Committee organised the second Exhibition of Professional Photographic Work, held from February 7 to March 7 in the gallery attached to the Office of the "Journal." On the experience gained from the previous exhibition it was thought advisable to proceed upon different lines; and on this occasion the Editor of the "British Journal" was asked to furnish a list of photographers of established reputation, who were invited to furnish eight examples of their work, and from this number six were selected for exhibition. The exhibition was a great improvement on the last, and afforded an opportunity of studying the methods and style of some of the leaders of the profession of great value to those who were able to take advantage of it. As the accommodation of the Gallery only permitted the work of nineteen exhibitors to be included, there remains a number of members of equal standing to those invited this time who may be relied upon to form an exhibition of equal merit upon the next occasion. The Committee have to thank those members who responded to their invitation to exhibit, and are particularly indebted to Mr. S. H. Fry, who undertook the work of mounting the exhibited photographs in *passee-partouts*.

The number of applications from members for advice and assistance in business difficulties continues large, and in most cases the aid of the Association has enabled the difficulty to be met successfully.

At the members' meeting in October a valuable paper was read by Mr. Edgar Scamell on "Advertising," which raised an interesting discussion; and at that in January, Mr. H. J. Comley lectured upon "Colour Photography from a Professional Point of View," terminating with a demonstration of one of the methods of producing three-colour prints. The thanks of the Association are due to both of these gentlemen for their instructive communications.

The Committee have to deplore the deaths of two of their number during the year under review. Early in December, Mr. Marc Jaccotte, Past President, died after an illness of some months, and the Association was thereby deprived of the services of a man whose energy and foresight it is indebted in a great measure to its present strength and prestige. His amiable personality and great business aptitude commanded the affection as well as the respect of all his fellow-officers. Mr. H. S. Mendelsohn died suddenly

ary. His long experience as a professional photographer was great value in the deliberations of the Committee. He was a regular attendant at the meetings, and his loss is sincerely regretted by all those who have worked with him.

The thanks of the Association are due to the Royal Photographic Society for allowing the meetings to take place at their house, to the Editor of the "British Journal of Photography" for publishing notices, reports, and other information relating to the Association. The Committee also wish to express their indebtedness to the Hon. Solicitor, Mr. Percy E. Marshall, for valuable assistance rendered.

By order of the Committee,  
ALEXANDER MACKIE,  
Hon. Secretary.

## Patent News.

process patents—applications and specifications—are treated in the Mechanical Notes."

The following applications for patents were received between March 9 and 14:—

CINEMATOGRAPHS.—No. 5,291. Improvements relating to cinematograph displays. William Edward Delves Broughton, 6, Bream's Buildings, Chancery Lane, London.

APPARATUS.—No. 5,336. Improvements in cinematographic and photographic apparatus. Alberto Lleo Pablo Audouard and Emilio Baradat, 51, Bedford Street, Strand, London.

PRINTING ON FABRICS.—No. 5,479. For reproducing from a photographic negative, photographs on textile fabrics, such as silk, cotton, satin, and the like. Francis Edward Alphonsus O'Rourke, Seward Road, Hanwell.

ROLL FILMS.—No. 5,641. Improvements in roll-films for photographic work. Edmund Seal Donisthorpe, 5, Southampton Street, Strand, London.

PRINTS.—No. 5,726. Improvements in or connected with appliances for use in drying photographic prints. Arthur Ferri Pollock, 58, St. Vincent Street, Glasgow.

STEREOSCOPES.—No. 5,742. Improvements in stereoscopes. Albert Edward Foote, 37, Essex Street, Strand, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

The specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

COLOUR SCREENS FOR COPYING GRAIN AND OTHER SCREEN-PLATE COLOUR TRANSPARENCIES.—No. 4,932, 1907. The invention relates to the copying of one screen-plate colour transparency or negative on another by contact or in the camera, and the inventor first discusses at length the difficulties caused by the non-registration of similar colour units when one colour transparency is printed on another.

The invention consists in the use of coloured glass screens (for printing or copying), through which, unlike the screens used for ordinary photography, bands of pure light are transmitted—that is, absorption bands of these filters do not overlap, but are separated by broad bands of absorption. These screens are used separately and successively for the illumination of the screen-plate positive or negative when printing, or all three may be combined into one by building up a banded filter of the pure colours. All that is required is to put the printing frame containing the coloured negative and the positive film at the bottom of a deep box (Fig. 1), and to expose this to the light coming through a trichromatic screen as shown in Fig. 2. The peculiarity of this trichromatic screen is that it consists of a series of coloured bands or mosaics of the three required colours, the sum of the surfaces of the different colours being proportional to the respective exposure times of the different colours. Thus, if the red required 1 sec. exposure, the green 6 sec., and the blue-violet 2 sec., each of the three bands could be formed as follows:—A red band 4 c.m. in width, a green band of 2 c.m. in width, and a blue-violet of 1 c.m. in width. By moving this back and forth during

exposure, the different monochromatic lights will be sufficiently blended. To ensure this blending, a ground glass can be placed between the trichromatic screen and the printing frame (Fig. 1).

If one wishes to obtain coloured diapositives by means of the copying cameras, correct timing of the three different images, at one exposure, can be obtained by inserting in the lens and in close proximity to or in the diaphragm plane itself, a screen, divided in sectors of the necessary colours, which sectors are proportional to the respective times of exposure required.

The above-described methods can be applied also to the making of colour prints on paper. All that is necessary is to back a colour-positive of suitable density with white paper, and, after

Fig. 1.

drying, remove it, if necessary, from its provisional support. It is essential that steps be taken to ensure absolute adhesion between the coloured grains or lines and the underlying photographic image, as any shifting of the one relatively to the others would falsify the colours. These paper prints are not brilliant in colour, but the blending of the colours is so perfect that, in some cases, this method can be satisfactorily applied.

Pure colour-screens can also be employed in conjunction with colour positives to obtain negatives from which plates can be made for three- and four-colour printing, and for this purpose it is necessary to make three successive photographs of the coloured grain or line photograph on distinct plates. One, representing the

Fig. 2.

red image, must be made by means of a screen which will transmit light coming through the red image, but will entirely absorb all the light coming through the other two images. The red image, which on the original grain or line photograph only occupies one-third of the surface, must be made to occupy the entire surface, either by a slight motion of one of the plates or by a slight diffusion of the image, as described in British Patent No. 8,390/96. The green image must be made by means of a screen transmitting light coming through the green image and entirely absorbing the light coming through the red and blue violet

images. Similarly, the blue violet image must be made by means of a screen which transmits light coming through the blue violet image and entirely absorbing the light coming through the green and red images. Both the green and blue violet image must be made to cover the entire plate. The images are then printed in colours complementary to the primary colours. That is, the red image is printed in greenish blue, the green image in bluish red, and the blue violet image is printed in yellow.

The present method of colour analysis differs radically from those hitherto known, for, as before noted, all other colour curves have one distinguishing feature, namely, they overlap each other two by two, while the distinguishing feature of the present method is that the curves do not overlap; furthermore, they are isolated one from the other, and are absolutely unfitted for the work of analysis of the colours required in ordinary methods of natural colour-photography. Charles Louis Adrien Brasseur, 10, East Fifteenth Street, New York, U.S.A.

**MAGAZINE CAMERA FOR FERROTYPED PHOTOGRAPHY.**—No. 21,669, 1907. The invention consists of a camera in which the sensitive plates are stored in a pile. The plates are brought one by one into the position for exposure by a magnet, and after exposure fall into the developing and fixing tank. The invention requires the seven figures and the detailed description of them for its proper explanation. Major William Carter, 167, Old Kent Road, London, S.E., and Edwin John Fletcher, 80, Geldeston Road, Upper Clapton, London, N.E.

**REFLEX CAMERAS.**—No. 5,411, 1907. The invention consists of a reflex camera in which lenses of long and short focus can be used, since the mirror is not arranged in the usual way, according to which it is hinged to the upper back part of the camera, and, when released from its "down" position has to fly up between the lens and the plate. Instead, the mirror falls, or is guided, into the bottom part of the camera, and there takes a

horizontal position. In the figure, A is the hood, B the focussing screen, and F the bellows of a reflex camera C. The mirror D has a rod  $G^1$  along its back edge, the two ends of which rod slide in and are guided by metallic guide-ways  $E^1$  at the sides of the camera, the said guide-ways being vertical or approximately so. At the front edge of the mirror there are lateral pins  $G^2$  engaging in the guide-ways  $E^2$  which are partly horizontal and partly inclined.

$H^1$  is a blind attached to the rod  $h$  which is fixed at the back lower part of the camera, and, passing over the rod  $G^1$ , is attached by means of tapes  $h^1$  to the spring roller  $K^1$  at the front lower part of the camera.

$K^2$  is a spring roller situated in the front upper part of the camera, and has one end of the blind  $H^2$  attached thereto; to the other end of the blind  $H^2$  are attached cords  $h^2$ , which pass over the roller N and are attached to the rod  $G^1$ .

The action is as follows:—To "set" the mirror a cord is drawn until the back edge of the mirror is pulled up and the end of the rod  $G^1$  catches and is held behind the nose of the lever J. The mirror is then held in a position inclined at an angle of 45 deg., and the ends of the rod  $G^1$  and the pins  $G^2$  occupy the upper parts respectively of the guide-ways  $E^1$  and  $E^2$ .

Whilst in this position the blind  $H^1$  covers the sensitive plate, and the field of view is reflected by the mirror on to the focussing screen B since the blind  $H^2$  is released and wound up on its roller  $K^2$ .

On depressing the lever M the nose of the lever J is withdrawn from contact with the end of the rod  $G^1$  and the mirror is enabled to fall both by its weight and under the tension of the tape  $h^2$ , which winds up on the spring roller  $K^2$ . As the mirror descends into a horizontal position (the ends of the rod  $G^1$  traversing the guide-ways  $E^1$  and the pins  $G^2$  the guide-ways  $E^2$ ) the blind  $H^1$  is drawn across the face of the mirror, its tapes being wound on to the spring roller, and at the same time the blind  $H^2$  is unwound off the roller  $K^2$  and is drawn across the focussing screen, the mirror falling on to the floor of the camera. Arthur Lewis Adams, 26, Charing Cross Road, London, W.C.

**PLATE OR FILM ENVELOPE.**—No. 15,711, 1907. The invention is for a light-tight envelope open at one end, and closed at the other by a cap which is retained in position by friction against the plate or film. The envelope does not press upon the surface of the film or plate over its whole extent, nor fit closely over it, but its edge may be pressed inwards to be inserted under the flaps of the cap, which will then be in contact with the inserted surface of the envelope near the edges over the whole of the depth of the edge of the cap, and will firmly retain the inserted edges in a light-tight manner and with sufficient frictional power, by reason of their being gripped or squeezed between the inner surface of the edge of the cap and the surface of the film or plate. There are thus no projecting edges by which the use of the cap may in any way cause inconvenience or liability to unintentional opening, but the whole presents a flush surface. Optische Anstalt C. P. Goertz, Aktiengesellschaft, 44-46, Rheinstrasse, Friedmann, Berlin.

**RELIEF EFFECTS IN PHOTOGRAPHS.**—No. 4,361, 1907. The method consists in first coating a glass or metal plate with a 20 per cent. gelatine solution. When dry, the plates are sensitised in 3 per cent. potass. bichromate solution. The dry plates are exposed under positive transparencies or negatives, and then soaked in cold water to swell the gelatine—or in solutions such as those of bromides, chlorides, or iodides, if a greater degree of relief is required. The gelatine relief thus formed is hardened with basic chrome alum solution, or with formalin, and used for the production of plaster matrices, or as a mould for wax matrices.

Reference is directed by the Comptroller of Patents, in pursuance of Section 7, Sub-section 4, of the Patents and Designs Act, 1907, to Specifications No. 6,690 of 1894, No. 14,814 of 1898, No. 10,948 of 1902, No. 18,210 of 1902, and No. 3,457 of 1904. Rodolfo Namias, 3, Via Malpighi, Milan, Italy.

The following complete specification is open to public inspection under the Patents Act, 1901:—

**COLOUR PHOTOGRAPHY.**—No. 4,745. Process of colour photography. Brasseur.

## New Trade Names.

**IVOR-MICA.**—No. 299,961. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives. Anton Rutherford Van Der Burg, Junior, Havenstrasse No. 154, Delftshaven, Rotterdam, Holland, merchant. January 28, 1908.

**JUPITER.**—No. 300,454. Electric lamps (ordinary). John J. Griffin and Sons, Ltd., Kingsway, London, W.C., photographic manufactures. February 13, 1908.

# Analecta.

Extracts from our English weekly and monthly contemporaries.

## A Remedy for Over-Printed P.O.P.

The following is a method of remedying over-printed proofs on ferro-chloride paper (writes "Photography"). This is a gold toning bath, which not only tones but at the same time reduces. The prints are washed in two or three changes of water, and are then immersed in the following toning bath:—

Water .....	1 pint.
Hydrochloric acid .....	100 minims.
Gold chloride .....	1 grain.

At first, the print on being placed in this solution changes colour and appears to stain very badly, but after the lapse of a minute the stains gradually disappear, and the yellowed image steadily passes to a satisfactory colour, having become reduced very considerably in doing so. When the action has been carried far enough, the print is washed in several changes of water and then dried in hypo.

As this toning bath is strongly acid it would no doubt be a wise precaution to give the prints, between toning and fixing, a bath for a minute or two, in a weak solution of bicarbonate of soda.

## New Books.

**THE WELLINGTON BOOK.**—Messrs. Wellington and Ward have issued a fifth (and much enlarged) edition of their "Notes on the use of the Wellington Specialties," a book of instruction in the employment of the plates, papers, and films manufactured by the well-known firm of Elstree. We have been interested in watching the growth of this booklet from the slim dimensions of the first edition to its present thickness of 100 pages, a growth which it is satisfactory to say has been synonymous with the increasing sale and popularity of the Wellington products. Messrs. Wellington and Ward offer to send the publication post free to any applicant, and will be particularly glad to do so in the case of foreign readers of the "British Journal." Their offer is one which we can commend to those anxious to obtain a great deal of useful information, concisely expressed. The notes on chemicals which occupy the last few pages are particularly useful, and give the clue to many unexplained failures in photographic work.

## New Apparatus, &c.

**Staley-Wheeler Collapsible Lens-Hood.** Made by A. E. Staley and Co., 19, Tavies Inn, Holborn Circus, London, England.

The lens-hood, which for some years past has shown a tendency to appear from the mounting of photographic lenses, has recently revived, owing to the necessity of shading the lens from direct light in the case of anastigmats which possess large aperture and are

of the air-space type of construction. A hood which actually cuts off light from the surface of the lens is a better method than the use of diaphragms in the camera, which aim to cut off the light transmitted by the lens, and for this reason satisfaction should be felt

that Messrs. Staley have devised an external lens-hood which comprises a series of diaphragms, but which folds up into the small space of about 1 in. thick by 3 in. diameter. The concentric rings which form the hood lock rigidly in position, and afford a complete protection against stray light. The hood should prove a valuable accessory to the user of both hand and stand cameras, and particularly to those who employ any of the modern air-space type of lens. The hood is made in two sizes: No. 1 for lenses up to 1 in., and No. 2 for those up to 2 in. diameter. The price of the former is 10s. 6d., and of the latter 12s. 6d. The brass mount of the hood may be provided with a thread, or rubber or cork adapters can be employed to attach the hood to the lens tube.

For the Staley-Wheeler high-power telephoto lenses, which Messrs. Staley are now placing upon the market, a special form of tube is made, 9 in. in length, and divided in the centre into two parts each 4 in. long. This form of construction is necessary for telephoto work at high magnification, but the simpler and more portable form of hood, which we have just described, should be sufficient for more moderate power telephoto and for the general run of photography.

**The Tenax Pocket Camera.** Made by C. P. Goerz, 1 to 6, Holborn Circus, London, England.

In their new folding pocket camera the Goerz firm have followed a design quite distinct from that of the universally known "Goerz-Anschütz." The Tenax is built with an extending baseboard which covers the lens and shutter when the camera is closed for carrying. The baseboard thus permits of considerable extension of the bellows, and in the quarter-plate camera sent us for examination the distance from lens diaphragm to plate is 10½ in. This, in a camera which closes to 1½ in. in thickness, evidences a careful construction. Another feature of the Tenax is the extending front. On the baseboard being let down, a pair of steel bands pull the front out to the position of focus for infinity, and in doing so coil themselves in a small barrel on the front of the baseboard. Thus,

to prepare the camera for a snapshot at infinity, all that is necessary is to open the instrument. For focussing nearer objects, the focussing scale is used in the ordinary way, and as the camera must be set back to infinity before it can be closed it is bound to be always in the same condition when opened. The camera is made for use with single dark-slides or with the film-pack adapter, which two pieces of apparatus are made interchangeable. The camera has considerable rise of front and cross movement, the latter, of course, being equivalent to rise of front when the "landscape way" of the plate is used. It is fitted also with reversible finder, and the Goerz "Sector" shutter, giving exposures from one second to 1-250 of a second. The whole mechanism is worthy of the reputation of the Goerz house for beautiful mechanical work, yet the camera costs, in the quarter-plate size, with Goerz Syntor lens and film-pack adapter, £8 8s.

**The Isostigmat Lens. Series IV. (wide angle), f/6.3.** Made by R. and J. Beck, 68, Cornhill, London, England.

This is one of Messrs. Beck's latest introductions, and, judging from the specimen submitted to us, it is likely to be a valuable instrument. The lens we have tested is of 4½ focal length and full aperture of f/6.3, and covers an angle of about 80deg., these particulars being according to our own measurements. It is intended for use on a quarter-plate as an ordinary lens, or for a half-plate when used as a wide angle. In the latter case the rising front can

be used to an extent of  $1\frac{1}{2}$  in., while in the former a rise of  $2\frac{1}{2}$  in. is available. The lens behaves exceedingly well in our hands. It has a very flat field, and the correction for oblique light is as strikingly perfect as in the older types of Isostigmatar. The prices are moderate, seeing that they range from £3 15s. to £5 5s. in a series

of five lenses of focal lengths from  $3\frac{1}{2}$  in. to  $7\frac{1}{2}$  in. A highly corrected wide-angle lens, with an aperture of  $f/6.3$ , is, of course, a most useful introduction to architectural photographers, for while it will generally be necessary to stop down to gain depth, yet the full aperture can always be used for focussing, which is a great gain in a dark interior.

Lancaster Long-Extension Cameras. Made by J. Lancaster and Son, Ltd., Broad Street, Birmingham, England.

Several models of a camera with a new pattern of extending front have been introduced by the well-known Birmingham firm, both in the hand-stand pattern, and in the usual type of stand camera. The figure shows the former in one position, from which it will be seen that the pair of double supporting struts permits, not only of any degree of swing to the front, but also allows of the front being raised until it is held perpendicularly over the fixed struts, a position

which gives a rise of front far in excess of what is likely to be required in everyday work. Moreover, when these special positions are not required one of the pair of sliding struts acts as a guide to the other, and allows of the front being raised or lowered perpendicularly to the camera base. The hand or folding pattern is sold in quarter-plate size at £3 10s., with one double dark slide, or for £4 15s., with one slide, "Unicum" shutter and Lancaster "Recti-plat" lens. The stand pattern in half-plate size with R.R. lens, roller-blind shutter, rotating turntable top, and one dark slide costs £4.

The "Heliar" Reflex Camera,  $3\frac{1}{2}$  in. by  $2\frac{1}{2}$  in. Made by Voigtlander and Sohn, 12, Charterhouse Street, London, England.

In adding a camera smaller than quarter-plate to the series of "Heliar" reflex instruments the firm of Voigtlander, we, think, has shown that it fully realises the advantages of the reflex type of instrument, and our own experience certainly leads us to the opinion that for a small tourist instrument the  $3\frac{1}{2}$  in. by  $2\frac{1}{2}$  in. size is preferable to the quarter-plate. The only condition which becomes even more stringent in the case of a small reflex camera is accuracy of workmanship, the smaller working parts calling for still better workmanship. In this respect it is impossible to find fault with the "Heliar" camera, which mechanically is a beautiful instrument, and most convenient and rapid in practical work. For the  $3\frac{1}{2}$  in. by  $2\frac{1}{2}$  in. plate a "Heliar" lens of  $4\frac{3}{4}$  in. focus is fitted, and the total extension from focussing screen to lens panel is 8 inches. Complete, with its lens and three double dark slides, the camera costs

£16 5s., or for £19 5s. is sold with one of the Voigtlander telephoto attachments, giving  $2\frac{1}{2}$  times magnification, and thus permitting

long focus pictures to be obtained at a working aperture of no greater than  $f/11$ .

"Oxys" Anastigmatic Lenses. Series II. Made by Aldis Bros., Old Grange Road, Sparkhill, Birmingham, England.

In this new lens of the well-known Aldis firm, the doublet form of construction has been retained—that is to say, the lens possesses only four reflecting surfaces, and is therefore free from liability to flare and ghost images which are less easy to avoid in lenses of many air-spaces. Also a doublet lens is

readily cleaned by the user without the risk of disarranging the glasses. Whilst retaining these advantages, Messrs. Aldis have aimed to secure (1) a more perfect correction for flatness of field, and (2) a "back focus" shorter or longer than the equivalent focal length of the lens.

The specimen sent us is No. 11 of  $5\frac{1}{4}$  focus and aperture  $f/5.6$ , both of which measurements we have confirmed. It is recommended for use on a quarter-plate, and it is stated to cover  $6 \times 4\frac{1}{2}$  with a medium stop. As a matter of fact, we find that an aperture of  $f/16$  is fully effective at the corners of the larger half-plate.

As regards the adjustment of the "back focus," or camera extension, as Messrs. Aldis prefer to call it, the lens we have examined requires 4.9 in. from the face of lens panel to the focussing screen for the above-mentioned focal length of  $5\frac{1}{4}$  in. A short extension

is, of course, often very convenient, but the makers of the "Oxys" have recognised the fact that a comparatively long extension is also often desirable, especially in reflex and magazine cameras. Therefore the new lens has been designed so that it will work equally well when turned the reverse way round. Several of the lenses on the list are so mounted as to give an extra long extension as compared with the focal length. The No. 10, for example, requires an

extension of 5.2 in., though its focal length is only 4.85. The following table gives the range available:—

No.	Focal length.	Camera extension at infinity.	Recommended for use on	Plate covered at medium stop.	Price of "Oxys" Lens mounted in:—		
					Iris mount.	B. & L. "Unicum" shutter.	B. & L. Automat shutter.
10	4.85	5.2	4½ × 3½	5½ × 3½	£3 0 0	£4 5 0	£4 10 0
11	5.25	4.9	4½ × 3½	6 × 4½	3 0 0	4 5 0	4 10 0
12	6.85	6.4	5 × 4	8 × 5	4 10 0	6 7 6	6 16 6
13	7.7	8.2	6½ × 4½	8½ × 6½	5 0 0	7 10 0	7 16 6
12a	6.85	6.4	5 × 4	8 × 5	3 10 0	4 15 0	5 0 0
13a	7.7	8.2	6½ × 4½	8½ × 6½	4 13 6	6 11 0	7 0 0

Those who desire a well-corrected lens of a useful type should be able to suit themselves from this list.

The No. 1A "Ralli" Folding Focal-Plane Camera. Sold by W. Butcher and Sons, Limited, Camera House, Farringdon Avenue, London, England.

In offering a camera of the convenient focal-plane type Messrs. Butcher have placed at the disposal of amateur users an instrument which opens out on its four nickelled struts to a very rigid position. The camera is fitted with cross and rising fronts, and carries a lens direct vision-finder of the usual type in addition to a full-size non-magnifying finder which folds up on front of the camera, and is a type of under which is as simple and efficient as any other. The shutter is arranged to work at two tensions, rapid and extra rapid, whilst the

operation in the width of the slit can be very conveniently made, being easy to increase the speed of the shutter at the instant before exposure within a range represented by 1-500 to ½ second. The times of exposures is clearly shown on the scale on the side of the camera, and the alteration of the speed is made just in the same manner and quite as easily as focussing by the usual rack-and-pinion focussing scale. The camera is fitted with lens working at  $f/8$ , in focussing mount, permitting all objects for infinity at two yards being focussed. The price complete with hooded focussing screen and two double dark slides is £7 7s.

Primo-plane Cooke Lenses. Made by Taylor, Taylor, and Hobson, Leicester, England.

Messrs. Taylor, Taylor, and Hobson have submitted to us two of their new Primo-plane lenses designed according to Mr. H. D. Taylor's patent specification No. 7,661, 1906, which we published in our issue of April 12, 1907. Reference to this shows that the meaning of the term "primo-plane" is flatness of the primary image surface; in other words, the lens is intended to render tangential rays sharply over a very wide flat field. The construction permits the use of a stop either in the interior of the objective or in front of the lens just grazing the front lens, and a specimen of each kind of construction has been submitted to us. The lens at present is made

only in the focal length of 5in., and it is intended for use as a wide angle lens on a half-plate. The aperture is marked  $f/6.5$  in both patterns, but our measurements show that the lens with interior stop is somewhat faster than this, while the other with front stop is a trifle slower. In fact, we make the one  $f/6.35$  and the other  $f/7$ . By reversing the lenses these apertures are respectively reduced to  $f/6.2$  and  $f/6.7$ , so that a variable rapidity may be looked for if the lens is used for enlarging purposes. It is, of course, not intended for such work, but as lenses are commonly put to all kinds of purposes by their owners, quite regardless of what their makers designed them for, it may be useful to point out this peculiarity. The central definition of these lenses is as fine as can be wished for, and they should prove most useful instruments to all who want wide-angled objectives of large aperture. The price of the 5in. lenses is £4 12s., and larger sizes can be made to order.

The "Sibyl" Pocket Camera. Made by Newman and Guardia, Limited, 90-2, Shaftesbury Avenue, London, England.

In the "Sibyl" Messrs. Newman and Guardia have produced a pocket camera indeed. It must be a couple of years or more since we saw the first working instrument, and we, with no doubt many others, have chafed at the delay in bringing the camera on the market. Procrastination, however, in this case is a virtue, since it is a sign of the makers' determination not to issue an article until it is as good as they know how to make it, which means a good deal in the case of the "N. and G." firm. Moreover, though many of the working parts of the "Sibyl" are machine-made, the fitting together of the instruments involves skilled hand labour, the result of which is seen in the smoothness of working and the accuracy of the movements. The outcome is an instrument which the makers can justly claim to be the embodiment of all the qualities which man can reasonably ask for in an instrument to be carried in his pocket, always ready for work, and yet of such size that he will not feel its weight or bulk any more than that of his cigar-case. To what extent Messrs. Newman and Guardia will do business with those who must have a small and yet perfectly practicable instrument can best be judged by pointing out that in the "Sibyl" they offer a camera which—

1. Measures 5in. by 3½in. by 1 3-16in., including the slide carrying a plate ready for exposure.

2. Is without a single projection or exposed piece of mechanism when folded for the pocket.

3. Permits focussing up to two yards, and can be set to come to any focus on opening the camera.

4. Has a vertical rise of front over one-third the length of the picture.

5. Carries finder showing an image over one-third the size of that obtained in the camera.

6. Is fitted with a shutter giving exposures from ½ to 1-100th second.

The general appearance of the camera, open and closed, will be seen from the two figures. The size of plate is the 3½in. by 2½in., and the dark slide is so made that the full plate is exposed up to the edges, with the exception of ¼in. at one end. As the figures show, the method of extension adopted in the "Sibyl" is the lazy-tongs, permitting the front to remain anywhere between its two limits of movement. The front is not dependent on runners for its guidance, and thus requires scarcely any inducement to leave the back, on the baseboard cover being opened. It locks gently into the catch on the focussing, and is then found to have fixed itself with very great rigidity—to an extent, indeed, which seems out of all proportion to the effort needed to attain it. Without a

single screw to twist or bolt to turn, the front clicks into a position which could not be more rigid if there were half a dozen struts to hold it.

The point at which it stops is controlled by the separate focussing adjustment—that is to say, the camera can be set to open in focus on any distance from two yards to infinity. This adjustment thus enables one to carry about the camera in readiness for work of any particular kind, say open landscape requiring the focus at infinity or figures needing it to be at about three yards. The camera can be closed whenever the adjustment for focus is set.

The front is provided with an amount of rise, which may surely be considered enough for all ordinary conditions—that is to say, the lens will rise over one-third the vertical height of the picture, a movement which is perhaps the most valuable a camera of this kind can have, since its very portability will bring it before all descriptions of subject. The finder is of the direct-vision pattern, and is turned up on the lens front in an instant. A collimator pointer on the back of the camera comes into position automatically, and disappears in the same way on the camera being closed.

The shutter of the "Sibyl" is made in the manner familiar to users of N. and G. cameras—that is, entirely of metal—and with pneumatic regulation. It is self-capping, and gives a range of exposures, specially tested and hand-marked, of from  $\frac{1}{2}$  to 1-100th second. The plates are carried in single metal slides, in which each is inserted quickly and fixed in place by spring catches, which will hold a cut film just in the same manner, and keep it fit without the assistance of a carrier. The dark slide—and the focussing when it is used—is held in place by a light spring, which quickly but firmly presses it into register. The arrangement is much speedier in practice than a pair of grooves.

A rapid glance over our specification of the camera's movements will, perhaps, suggest the thought that neither the latter nor the means taken to obtain them constitute any novelty in photographic manufacture sufficient to justify a notice of the above length. But that criticism leaves out of account the extraordinary small bulk to which Messrs. Newman and Guardia have reduced an instrument possessing a list of movements which includes practically all that is required of a camera. That they have achieved this end by a simple method of construction should argue all the more for the popularity of the camera, which, as a matter of fact, is free from complicated mechanism, and has no working parts at all that are not easily accessible. We have never handled a camera which came near the "Sibyl" in the combination of practical efficiency and slim dimensions. The price of the camera, with "Cooke" Series III. lens ( $f/6.5$ ) of 4.4 in focus, and with six dark slides in leather case, is £9 9s. If a Zeiss II. B Tessar ( $f/6.3$ ) replaces the "Cooke" the price is £10 10s.

Thus far we have spoken of the  $3\frac{1}{2} \times 2\frac{1}{2}$  camera, a size which we ourselves prefer to the quarter-plate. However, in response to a demand for a slightly larger instrument, Messrs. Newman and Guardia have just brought out a quarter-plate size of the camera which is very little larger than its forerunner—it measures  $6 \times 4\frac{1}{2} \times 1\frac{1}{8}$  in.—and is in every respect on a par with the smaller size. The quarter-plate is fitted with the Zeiss Series II. B Tessar,  $f/6.3$ , of  $5\frac{1}{8}$  in. in focus, and costs, with six slides in leather case and focussing screen, £14 14s.

The Hermagis Anastigmat. Sold by Mr. F. C. Clarkson, Colchester, and 4, Fenchurch Avenue, London, England.

This is an extremely rapid lens, suited for portraiture, groups, enlarging, and for high speed hand camera work, and it appears to be remarkable for its fine quality and low price. A  $6\frac{3}{8}$ -inch lens, working at  $f/4.5$ , and covering a half-plate well, is not often to be obtained for £6 15s. The specimen submitted to us is No. 7A, of  $6\frac{3}{8}$  inches focus, and full aperture, according to our measurements of between  $f/4.5$  and  $f/5$ . It covers a half-plate excellently, and should therefore be extremely well adapted for use in a quarter-plate reflex camera having ample rise of front. The lens is apparently of symmetrical construction, and the single back component gives excellent definition when stopped down a little. The complete doublet is remarkably well connected, and there is no doubt whatever that a purchaser of this lens gets wonderfully good value for his money. A 5-inch lens, with iris diaphragm, is only £4 17s. 6d., or less than the cost of many other anastigmats of less than half the speed. The lens is listed with both iris diaphragms

and with Waterhouse stops, and it can be supplied in focussing mounts at an extra cost of from 17s. 6d. to £1. It is specially recommended for photography in colours, from which we may infer that special attention has been given to its chromatic corrections.

Lizars' Cameras. New Models. Made by J. Lizars, 101, Buchanan Street, Glasgow, Scotland.

The 1908 model of the excellent hand-stand "Challenge de Luxe" camera shows the still further improvements which have been made in this apparatus—namely, that the reversing back is now replaced by a rotating back, making the cameras as well nigh perfect as can be expected of human care and ingenuity.

The latest introduction by Mr. Lizars is a stereo postcard camera, size  $6\frac{1}{2}$  in. by  $3\frac{1}{2}$  in., of the well-known "Challenge" de Luxe reflex camera, of which we have in the past been compelled to speak in appreciative terms. The new size is an instrument which, while convenient for the general purposes of the tourist, takes a picture

which is large enough for press purposes, and is, moreover, a very convenient size for stereo work. Closed, the camera measures outside 8 in. by  $7\frac{1}{2}$  in. by 6 in., and, whilst having all its working parts covered, such essential portions of the apparatus as the focussing screen, mirror, and the lenses are instantly got at. The lenses as arranged for stereoscopic work may be given any necessary separation, which is shown by the scale on the lens panel, and in other respects the camera has all the good points of the well-known type of reflex. With three double book-form dark slides, carrying plates  $6\frac{1}{2}$  in. by  $3\frac{1}{2}$  in., and with a pair of 6 in. Beck symmetricals working at  $f/8$ , the price is £18 17s. 6d. One point which should not be overlooked is the ingenious stereoscopic division, which is made in two parts, hinged top and bottom, and thus lies perfectly flat out of the way when the camera is being used for panel or postcard pictures.

We may also refer to the special tropical models of the "Challenge" stand cameras, double extension instruments, with the full range of movements, rising, falling, and swinging front, swing back, wide-angle movements, and rotating turntable top, etc., which are obtainable in several patterns, built in teak and brass bound, specially for users in the tropics, a specialty of Mr. Lizars in all patterns of his cameras.

The "Multisecto," No. 2. Sold by Jonathan Fallowfield, 146, Charing Cross Road, London, England.

Some months ago we reviewed the new repeating back introduced by the firm of Fallowfield primarily for attachment to a studio camera, and we then expressed our good opinion of the facility afforded by it for the making of midjet and other small-sized photographs, on plates of the standard sizes. The success of the apparatus is no doubt the cause of "Multisecto No. 2," which is destined to perform a similar duty not only in the studio but afield, inasmuch as it is made for fitting to an ordinary half-plate camera. In taking it into use it replaces the reversing back, and in the case of three types of camera—the Fallowfield Alacrity, the Thornton-Pickard Imperial, and the Houghton "Victo's"—nothing more is necessary than to detach the reversing back and place the "Multisecto" in position. The dark-slide of the camera equally fits into the groove of the "Multisecto." Practically any half-plate camera will carry the "Multisecto" after a trifling adjustment. In order

g, the reversing back and a dark-slide should be sent to ensure correct cutting of the apparatus.

Those who have seen the older model or descriptions of it need not be told that the principle of the apparatus is the use of a "Secto," or mask, which is placed in the proper position by means of a notched bar, adjusted from outside the camera. By this means, once the subject has been focussed the whole series of exposures on one plate is made without inspecting the ground glass, and the

Fig. 1.

vision of the plate is done very accurately and quite automatically. In some respects the No. 2 pattern is an improvement on its predecessors. For example, some "Sectos" are fitted with sliding metal as shown in Fig. 1; each row of pictures thus commences at the same level. The *modus operandi* is as follows:—

When a photograph is required, say, with No. 5, which takes five midget pictures on a half-plate, the No. 5 "Secto" is put in position and the subject correctly focussed on the screen, the notched bar No. 5 is placed between the grooves and the slide is pushed along to the first catch-point, when the slide may be pulled partly out, then the spring bolt should be allowed to lock in the first hole and exposure made, and a further notch given till five movements and exposures have been made. Care should always be taken to see that the shutter of slide clears by a few inches the end of the "Multisecto." After five horizontal moves the slide is pushed

tures on his half-plate to two only. We illustrate an excellent example of one-third exposures, and would refer the reader further to the new "Multisecto" circular, which gives all the necessary particulars as to the numerous mounts also obtainable. The price of "Multisecto" itself, with nine "sectos," and a set of notched guide-bars, is 60s.

The "Sickle" Reflex de Luxe. Sold by O. Sichel and Co., 52, Bunhill Row, London, England.

In this example of the reflex principle in hand cameras means are provided for keeping the mirror always in the down position unless advantage is taken of the locking lever, which keeps it up for time exposures. The mirror being thus locked up, the focal plane shutter may be employed by pressing on the ordinary release to open, and again pressing to close, the shutter working very smoothly. Alteration in the width of the slit is very conveniently done with the winding key, and a series of exposures from  $\frac{1}{4}$  second to the most rapid are obtainable by adjusting the spring tension and the width

of the slit aperture. The camera is provided with a very convenient hood, rising front, and has a good extension. It is also fitted with a rotating back, which locks in both a vertical and horizontal position, and has as well a hooded focussing screen, so that, when such is necessary, it may be used held level with the eyes and the image focussed direct upon the ground glass. The price of the camera without a lens is £10 in the quarter-plate size, but Messrs. Sichel issue it fitted with their  $f/6.8$  "Fulmenar" anastigmat lens at £12 10s.

The "Profex" Dry Mounting Press. Sold by J. J. Griffin and Sons, Limited, Kingsway, London, England.

The acknowledged practical and satisfactory process of mounting

photographs to-day is the dry-mounting method. The advantages of cleanliness, perfect adhesion, and the fact that the mounts remain perfectly flat are so important that for all good class photography wet mounting must disappear. With this in view, Messrs. Griffin

Fig. 2.

er of the "Secto," and the space altered to the bottom when the camera is tilted or lens lowered, so that the subject to be taken will again appear in the focussing screen, and the operation is repeated. When once the idea of the movements has been obtained, the "Multisecto" will be found extremely easy to work; each "Secto" follows the above operation, but each has different moves; Nos. 13, 19, and 20 move horizontally so that it is only necessary to focus once.

Not only for portraits, but for landscape work, and particularly making the most of Autochrome plates, the new "Multisecto" would be a most useful and popular instrument. As supplied by Fallowfield, the size of the pictures can range from 3 x 2 in. to 4 x 5 in., a total number of eleven different shapes being obtainable. It is to say, the worker can ring the changes from eighteen pic-

have in their "Profex" machines produced a very practical apparatus at a moderate price.

This machine is large enough to meet the needs of most professionals. The size of the platen is 20 by 14, and it is possible to insert a mount 22 inches wide, so that with a single pressure one can mount a print, size 20 by 14, or with a series of pressures any print that is not more than 20 inches wide. The special feature of the machine is that the combined heating chamber and platen is hung loose on the capstan-head screw, so that when the wheel is turned the platen travels down and finds its own level, thus any little unevenness in the thickness of mounts will not interfere with the correct working. The price for the machine, complete with gas heater, is only £7 18s. 6d. Messrs. Griffin also supply all accessories, such as fixing-iron, spirit lamps or Bunsen burners for heating fixing-irons, adhesive tissue, and zinc plates for placing over the prints while mounting.

**Stand Cameras.** Made by the Camera Construction Company, Eagle Works, Durham Grove, Hackney, London, England.

Of three models of half-plate camera sets submitted to us by the Camera Construction Company we specially select the "Eagle" triple extension as a half-plate instrument, possessing all the modern movements, and obtainable, complete with lens, shutter, and tripod, at the reasonable price of 70s. The camera is fitted with rack and pinion adjustment for both back and front, it has swing and reversing back, swing and rising front, in addition to an ample cross front movement. In a number of minor respects, such as catches, turntable, and automatic stops, it is a convenient instrument in practice. One good feature is the shape of the bellows, which, even with the front raised to its maximum, does not cause any cut-off of the subject on the plate. The camera is certainly an excellent instrument for general photography, and particularly for the tourist, to whom excessive weight is a consideration.

The "Falcon" camera, which is made only in half-plate, at 60s., has the movements of the triple "Eagle," save only the extension, although the supporting struts permit almost as great an extension as with the more extensive apparatus.

In the "Condor" set rather more than the usual double extension is provided. There are self-erecting front and wide-angle movements to the back body, the price in half-plate size being only 57s. 6d. This set is obtainable also in quarter-plate and whole-plate, and all three are certainly most reliable instruments and extremely good value for the money asked for them.

**The Lancaster "Plano" Reflex New Model.** Sold by J. Lancaster and Son, Ltd., Broad Street, Birmingham, England.

We have reviewed in the past the reflex cameras issued by this

well-known pioneer firm in amateur photographic requisites, but the new model illustrated here will be seen to have a construction which

sharply marks it out from other instruments on the market. The back portion of the camera containing the focal-plane shutter and mirror mechanism is on the customary lines of a reflex, but the extension is practically that of an ordinary camera, and possesses a latitude of movements which it is difficult to secure in a camera which is the box form throughout. The new model is made in two patterns, one a double extension giving 9 inches between lens and plate in quarter-plate size, and the second a triple extension, giving a total distance of 15 inches in the quarter-plate size, a corresponding extension being provided in the 5 x 4 and half-plate sizes. Both models are very well made, are fitted with reversing back, considerable rise of front, and are obtainable with various standard anastigmat lenses. Without lens the camera in the quarter-plate size costs £5 5s. in the No. 1 pattern, and £6 6s. in the No. 2.

**The Tropical "Una" Camera.** Sold by James A. Sinclair and Co. Ltd., 54, Haymarket, London, England.

Of the "Una" hand-stand camera as an instrument of the best design and workmanship we have had occasion to speak in the highest terms. It is what one expects of Mr. J. H. Sinclair, and of his business policy of supplying only apparatus which he, good photographer that he is, can conscientiously recommend. The "Una" shows in a dozen ways the determination of Mr. Sinclair's firm to consider first the practical working qualities of his instrument, and though it is equal to the widest range of work, it is an instrument of few movements and working parts. This, however, by way of reference to the pattern of the "Una" made specially

for users in tropical countries. The body is of teak, French polished, instead of leather-covered, and brass-bound. These variations from the home pattern make the instrument capable of withstanding the severities of hot and moist climates and the attacks of tropical insects. The pattern is sold at an increased cost of 10s. in the quarter-plate size, 15s. in the 5 x 4 in. and 9 x 12 cm., and 20s. in the half-plate and 7 x 5 in.

**The "Mite" de Luxe Reflex.** Sold by A. E. Staley and Co., 12, Thavies Inn, Holborn Circus, London, England.

This reflex camera for a  $3\frac{1}{2} \times 2\frac{1}{2}$  plate is in many respects similar to the "Royal" reflex, with which Messrs. Staley's name is favourably associated. The mirror is made to fall automatically into the down position, and is "locked up" when giving time exposures or using the mirror in the ordinary way. The arrangement does away with the danger of uncovering the plate without rewinding the shutter. The focal-plane shutter has convenient adjustment of width of slit and tension of spring, and a widest range of exposures can be given with it, the adjustment in all cases being made from outside the camera. The extension is  $7\frac{3}{4}$  inches from lens panel to plate, and lens of as short a focus as  $4\frac{3}{4}$  inches can be used. The camera has rotating back, rising front, and convenient collapsible hood. It is sold with six single metal dark slides at seven guineas. Messrs. Staley fit it with their well-known "Euryplan" and other anastigmat lenses. A camera of this small size, it may be added, is particularly to be recommended when of the reflex pattern, inasmuch as the subjects can be very accurately included on the plate, so that for lantern slide making and enlarging a  $3\frac{1}{2} \times 2\frac{1}{2}$  negative is as useful, indeed more useful, than quarter-plate.

The "Royal" reflex, also of Messrs. Staley, possesses the same range of movements, and is a type of instrument well suited for professional work.

Audio Backgrounds and Accessories. Sold by F. E. Jones and Co., 22, Gray's Inn Road, London, England.

The great improvements which have been made of late in the backgrounds at the service of photographers were evident to us the

[Registered Design.]

er day on inspecting a series just introduced by Messrs. F. E. Jones and Co., a distinctive feature of which is the excellent com-  
mise which has been made between picturesque character in the  
ground and subjects before which an ordinary every day sitter  
be appropriately posed. Messrs. Jones have commendably got  
y from the tapestried salon and the gateway of the ducal castle,  
instead have given us a series of backgrounds, with accessories  
match, which go well with the ordinary persons who form ninety-  
out of a hundred of the photographer's sitters. This, we say,  
have done while still retaining highly picturesque qualities in  
the grounds and accessories. Both are issued at remarkably  
erate prices, the average price of a background 6ft. by 6ft. 6in.  
g 27s. 6d., or 50s. 8ft. by 8ft. We select one example (accessory  
background complete £5 10s.) to illustrate these modern introduc-  
s, and recommend professional photographers to write for photo-  
s illustrating the very large variety.

Tropical "Excelsior" Hand Stand Camera. Sold by W. Butcher  
and Sons, Limited, Camera House, Farringdon Avenue, London,  
England.

is is an instrument with a wide range of movements, yet pos-

g two qualities which are all-important to the worker purposing  
e it to foreign countries. In the first place it folds up very

compactly, and in the second has ample range of movements as  
regards rising front, extension, etc., to enable it to deal with prac-  
tically every subject. The woodwork is of teak and the metal parts  
of brass, where a metal of this strength is needed, whilst aluminium  
is also used to reduce the weight. The bellows, which are fitted  
with supporting strut, are specially treated to withstand the attacks  
of insects. The construction and design of the apparatus and its  
neat brass binding and other attachments make it a most suitable  
apparatus for use in trying climatic conditions. It is sold in quarter  
and half-plate sizes at £6 and £7 15s. respectively, which prices  
include two focussing scales engraved with distances for both the  
complete lens and the single combination, brilliant finder with hood  
and spirit level attached, and three double dark slides. Special  
mention should be made of the rack-and-pinion cross front and rising  
front movements, which enable the lens to be displaced in every  
direction with the utmost nicety.

THE WATSON "SILENT" STUDIO SHUTTER.—A new model of this  
shutter is now issued by Messrs. W. Watson and Sons, 313, High  
Holborn, London, England, the semi-circular bellows pattern being  
retained, but a new device for the release being adopted. This latter  
is actuated directly by the antinous metal release, and allows of the  
shutter being operated with ease and certainty with one hand. The  
new pattern of shutter is sold at the same price as its predecessor,  
or the new arrangement can be fitted to an existing shutter at the  
price of 8s. 6d., including six feet of flexible connection. The  
prices of the shutter range from £1 6s. for 3-inch opening to £2 7s. 6d.  
for 8-inch.

THE MULTI-SCREEN.—Professional photographers and others hav-  
ing need to keep prints and portraits at hand for display will be  
interesting in perusing the illustrated circular of the "Multi-  
Screen," the device of Mr. E. Webster, of 101, High Holborn,  
London, W.C. The Multi-Screen consists of a series of hinged  
screens, light but strong, and containing within themselves the  
means for hanging pictures or any part of them. They can also  
be covered in any desired style to accord with existing decoration,  
but their chief recommendation is the large hanging area they pro-  
vide in an astonishingly small compass. Not only this, but pic-  
tures are kept cleaner than when on a wall, and are very quickly  
displayed to full view. Prices of the screens, which can be made  
of practically any size, are obtainable from Mr. Webster at the  
above address.

THE POSTCARD "CORRESPONDENT'S" CAMERA.—A postcard size of  
the substantial correspondent's camera has been added by Messrs.  
J. H. Dallmeyer, Limited, to the series of instruments already well  
known for their solid construction and excellent workmanship. The  
"Correspondent's" is a camera for hard wear and trying work. The  
range of movements in the way of rising and swinging front, swing

and reversing back and extension is all that is necessary in ordinary  
work. Thus the rising front movement is 2½ inches above the normal  
position, and the camera permits also of the use of wide-angle lenses.  
The new size should gain all the popularity of its predecessors. The  
price of the camera is £7 5s., brass-bound £1 5s. extra, with three  
slides.

PLATE SUPPORTS FOR STAND DEVELOPMENT.—Mr. F. C. Clarkson,  
of Colchester, England, has just issued a little device which is  
certain to be of frequent use in the dark-room. While primarily  
intended to permit the novice in stand or time development to work  
this process in the ordinary dishes (the supports allowing two plates  
to be placed safely, one film down and the other film up, in the  
dish), it is easy to see that for many operations other than develop-  
ment the inverted position of the plate would be an advantage, and  
the metal supports therefore, which are sold at a price of 1s. 6d.  
per pair, each being 4½in. in length, are a recommendable addition  
to the dark-room outfit. With three pairs of supports four half-  
plates or eight quarter-plates can be developed in a 10 x 8 dish, and

the supports, being of white metal, are not liable to corrosion by photographic solutions.

**THE DALLMEYER "NATURALIST'S" REFLEX.**—This special form of the Kershaw reflex camera adapted by Messrs. J. H. Dallmeyer, Ltd., for telephoto work, has been modified for the present season by making the body smaller and providing the extension necessary for high-

power telephoto work by means of a rigid supplementary tube. The alteration has the advantage that the camera is thus suited exactly for ordinary work, and that the telephoto extension is obtained in the most rigid manner. The price of the new model remains the same.

**AIROSTYLE NEW MODEL.**—Mr. Autholtz, of the Airoystyle Syndicate, Limited, 35, St. Bride Street, E.C., has submitted for our inspection an improvement on their first model, although there seemed little fault to find with the original pattern. The new one is certainly a marvel of accuracy and smoothness of movement. The finger-piece, which was previously fixed at the side of the airoystyle, is now on the top, which seems to be preferred by many artists. The finish

of the airoystyle is undoubtedly perfect, and its strength allows of quite rough usage without the probability of its getting out of order. The Airoystyle Syndicate, Ltd., are manufacturers also of all classes of air-brush up to the largest instruments used for industrial purposes. One pattern may be appropriately referred to, namely, that supplied for applying lime and colour washes to wall and roofs, and therefore of interest to photographers undertaking any work such as whitewashing a wall or the studio roof. An air-brush works very quickly compared with application by hand in the ordinary way, and the apparatus sold by the Airoystyle Company at £7 15s., complete with rubber tubing, hand-piece, and the necessary tool, might conceivably be an economical investment to those compelled by force of circumstances to carry out such work for themselves.

**MINIATURE FRAMES.**—The photographic miniature—whether by the ceramic process (which gives the miniature in its highest form) or by the carbon or other processes, which, nevertheless, are capable of producing pleasing results—being a profitable branch of a photographer's

business, it is particularly gratifying to us to draw attention to beautiful miniature frames made by the Art Photographic Supply Co., Grosvenor Buildings, Steelhouse Lane, Birmingham. A number of these lie before us, and we can sincerely commend them to makers of miniatures, whose results must be very good indeed be worthy of the fine setting which is thus available. It was Sir Humphrey Davy at the Royal Academy who once exclaimed, "What an extraordinary collection of fine frames," and the remark might appropriately be repeated in reference to many examples of framed photographs. However, to instance one or two of the productions of the Art Photographic Supply Co., we would take, for example, No. 503, a frost-gilt, hand-made, reeded frame with frost-gilt metal mat and supporting strut, the price of which to take oval 3 x 2½ in. is 8s. 6d. Another choice pattern is the "Hilliard

the No. 2 size of which has an oval opening of 2 x 2½ in., and consists of frost-gilt surround ornamented with scroll work. The company also make a special feature of circle and oval frames, plain or ornamented and supplied complete in beaver leather case, the workmanship being extremely nice, and yet issued at most reasonable prices. For example, No. 33, 1½ in. circle, in red beaver case, is priced at 9s. 6d., whilst an oval frame, with opening 2 x 1½ in., costs, in green beaver case, 7s. 6d. Still another example of the firm's work, which, like the preceding, is wrought throughout their own workshops, is a hand-hammered copper case made with folding doors and copper back, fitted with copper mat and copper fastening; this, with an oval opening of 2 1-10 x 1½ in., costs 4s. All the above, which are only examples of many patterns made by this Birmingham firm, form exceedingly handsome presents, and the full price list, which illustrates many of the patterns, should be consulted by those employing, as they profitably may, the miniature in their business.

## New Materials, &c.

Ilford "Carbon Surface" and "Glossy" Bromide Papers, White and "Ivory." Made by Ilford Limited, Ilford, London, England.

During the past three weeks we have made a considerable number of prints and enlargements on these development papers newly issued by the Ilford Co., each in a white and an "ivory" (cream) colour, and thus amounting in all to four new papers. In writing of our experience we will refer first to the "carbon" paper, which is, of course, a quite distinct paper from the "glossy," although the depth of "ivory" or cream tint, to judge from the prints before us, is the same in each. In examining the very pleasing texture of the prints we cannot help being reminded of the first Ilford bromide paper which we used about the year 1889 or 1890, at the time, we believe, of its first introduction. Many other users then (and still then) of Ilford products will bear us out in our impression that the smooth Ilford bromide paper of twenty years ago was very similar in surface to the "carbon-surface" paper which is now before us. The whirligigs of fashion often bring us back to the same point again, and though an exact comparison of the two papers would be a short of justice to the newcomer, the resemblance in surface, unless we are mistaken, is quite marked, and conveys the satisfaction that in offering photographers a paper which is at the present

time in great demand, the Ilford Co. are drawing on an experience of a score of years and more, and adding another entry to their long and distinguished record. So much for reminiscences. Our object, however, is to write of the new paper as we have found it—namely, a bromide paper with the notable excellences of pure whites, a wide scale of tones, and the rich surface of the semi-matt kind, characteristic of a carbon print as ordinarily produced. The production of these qualities simultaneously in the same material implies technical skill of a high order, but certain it is that the Ilford makers are in their possession of it. In the white variety of the papers one can get all the brilliance one wants. The “ivory” variety gives a somewhat softer effect, the full beauty of which, to our mind, is brought out by sulphide or similar toning. The fact remains that without altering one iota of his method the photographer can obtain a looking rich vigour on the white paper and the softer nuances the “ivory.” It is no derogation to existing Ilford bromides to ascribe the new paper as a valuable addition—the series is made up of distinct numbers—but it is satisfactory to find that the Ilford Co. adhering to its policy of holding back the issue of a new paper until they are satisfied that the product is as good as can be made. We have no hesitation in pronouncing this as our opinion in reference to the present paper.

Of the glossy paper—also white and “ivory”—we are bound to say the good things we have written of the “carbon surface,” with the additional comment that in our very fair use of it we have not experienced any of the scummy and hair-like markings not uncommon on glossy papers. The white paper in particular commends itself as for prints intended for reproduction, whilst the “ivory” paper, sulphide-toned, gives the handsome appearance esteemed by, and familiar to, the young person who purchases the picture postcards for their idols in the shops. We should add that all our results were obtained with the usual amidol developer—whether that recommended by the Ilford Co. or not we have no idea. It should also be stated that the new papers are issued at the standard prices.

**“Artista” Matt-Surface Paper.** Sold by Houghtons Ltd., 88-89, High Holborn, London, England.

To those who realise the condition of professional photography in this country, and its cleavage into the very good and the fairly commonplace, there is no need to explain the advantages of a printing process on which are obtained results of distinctive beauty, and in regard to which measures are taken to secure it from vulgarisation into the hands of the great mass of photographers of the amateur and semi-amateur classes. In other words, a good deal is to be said for a paper which is so issued that it is not likely to be purchased by every amateur maker of photographs which in the main are but passable, and which, in itself, is sufficiently a thing by itself as regards manipulation to be out of the reach of the man whose photographic attainments stop short at P.O.P. or even gaslight printing. Such a paper, however, would fail to fulfil its avowed object of providing the really skilled photographer with a means of giving his customers distinct effects if the results obtained on it were not of the highest order. Considerations such as these must be borne in mind in any evaluation of the step taken by Houghtons, Ltd., in introducing a paper which is offered directly to the professional photographer, and intended for use practically by him alone. Yet it is not too much to affirm that qualities such as we have outlined above are embodied in the new “Artista” paper just issued by Messrs. Houghtons, and our experience with the new introduction, and some account of the circumstances of its supply, may therefore be not without interest.

The “Artista,” we would first explain, is a paper with a natural matt surface, due to the fact that the sensitizing compounds are not wholly on the surface, but are held in the films of the paper, with the result that the natural texture of the latter is obtained in the print. Proof of impregnation of the paper in this way is supplied by exposing the reverse side to light, when an image of considerable intensity is obtained. Moreover, the finished print, however dry, does not crack when folded, there being no enamel-like film in the paper. The paper, in short, is innocent of an emulsion film, or if any such layer there be, it is of such a thin and elastic nature that the paper, in practice, may be treated as a “plain” sensitized material such as is in universal use before the days of emulsion-coated papers. These are, however, factors in the mechanical treatment of the prints, though they imply great freedom in handling they convey little to the actual results obtainable.

To come first to the surfaces and weights of “Artista” paper obtainable, there are in all eight varieties, all amenable to the same toning and fixing baths, and including among themselves a range of effects which we should judge to afford a professional photographer all the latitude he can desire. The “smooth” paper is supplied in two weights (Nos. 1 and 3). The former is the standard make of the paper, and is of the stoutness suitable for prints to be mounted. The latter (No. 3) is a fairly heavy paper, well adapted for attachment by two corners to the folder type of mount. The surface is a fine surface, not to be described as matt, yet without the sheen which is a characteristic of many papers now largely used. It is certainly smooth, though the word alone does not do justice to the delicacy of the surface. The No. 2 is “thick rough,” yet is a paper not too rough for small work. All three of this trio are white papers, which look particularly well when toned to black by the gold-platinum bath, of which later. Nos. 4 and 5 are thick cream papers—No. 4 rough, and No. 5 smooth; whilst in Nos. 6 and 7 we have two papers (both white), the former known as “fine-screen grain-surface,” and the latter as “coarse-screen grain-surface,” and both of minute webbed pattern, which is of great advantage in giving life to the shadows, and is most serviceable in dealing with dark heavy subjects. The finer of the two grains is very fine; the coarser for broader effects is just noticeable enough when a print is held about 15 inches from the eye, from which may be judged the size of work for which it is most adapted. Lastly, we have the “Artista” vellum, with the natural beauty and “coolness” of this material. So much for the textures of the sensitive materials, the best description of which falls short of the originals, and prompts one to run the pen through what has been written, and merely refer the reader to Messrs. Houghtons’ offer to send selections of the papers to bona-fide professional photographers at a nominal price.

In the matter of toning the notable features of the paper are: 1. The number of fine tones obtained with a few baths; and 2. The quickness of the processes. Selecting Grades 1 and 4 (“smooth white” and “thick cream rough”) for our trials, we soon satisfied ourselves as to the ease with which a great range of tones is obtained. In every case washing in five or six changes of water should precede the toning process, after which, five minutes’ immersion in a weak salt bath produces a rich warm tone of reddish brown, showing, as do the prints by all the toning processes, fine gradation, from the brilliant high-lights to the dark tones of the shadows. A very short toning in acetate-carbonate gold bath gives a rich warm sepia, whilst an ordinary platinum bath used after immersion of the prints in weak ammonia (and thorough washing) gives a cool brown tone. A colder tone still—warm black—is given by platinum toning following a short salt bath, and, finally, for the coldest tones, a few seconds dip is given in a tungstate gold bath, and a further toning applied in the platinum solution. The above operations have pleased us by their rapidity, and the results must surely gratify any photographer as much as they have done ourselves, whilst as for variety of results—a range of, say, five sufficiently distinct tones and eight varieties of paper—what more can man desire?

Because our own results have shown us the rich prints and beautiful tones, without a sign of double toning; because the surfaces are distinct and aesthetically pleasing; because they lend themselves to spotting and working up like a platinotype, for these, if for no other reasons, the paper may be described as a power in the hand of the professional worker. There are other reasons, too. Messrs. Houghtons issue the paper either in large sheets or gross packets of cut sizes, a provision which attaches the sale to the professional worker. Hence on two accounts there is good reason for our again reminding our readers of the present special offer to bona-fide professional users.

**XL Bromide Papers.** Made by B. J. Edwards and Co., Castlebar Works, Ealing, London, England.

A notable item in this Colonial issue of the “B.J.” is the appearance on the market of photographic printing papers made by the old-established firm of Messrs. B. J. Edwards and Co., who will be remembered as the first makers of an orthochromatic plate under the Taillier patent of now some thirty years ago. The management of the firm having some months ago been placed in the hands of Mr. E. J. Wall, F.R.P.S., the outcome has been, first, improvements in several respects of the Edwards’ plates, and, now, the introduction of a series of printing papers of some very considerable interest. Our purpose here is to mention the bromide papers made in five grades, namely,

"smooth glossy," "matt," "regular grain," "cream canvas," and "natural surface." Of these the matt and glossy papers call for no special remark, except that our own trials of them have shown them to be papers giving very pure whites and good gradation into the intense rich blacks. The chief interest, however, attaches to the other brands of paper, and particularly to the "regular grain," which is a paper with a peculiar minute dotted surface which gives a singularly pleasing effect not only in portrait subjects, but for landscape work, and is particularly useful in breaking up hard masses of shadow and removing what would otherwise be an eyesore in a print or enlargement. The "natural surface" paper is very appropriately titled, inasmuch as it does not suggest in its appearance the surfaced effect of an emulsion paper, but looks more like a wash drawing on a fine variety of Whatman drawing paper. We have found this paper most suitable for subjects of comparatively light tones, in which work it gives the most pleasing effects, and those of a kind which are a welcome change from the matt and semi-matt effects usually given by bromide prints. The "cream canvas" is a paper for big effects, and under 15 x 12 size we should hesitate to use its realistic canvas surface. The tint of the paper is a faint cream, and the canvas effect obtained with it may be described as a thorough means of breaking up masses of dark shadow, and of giving to subjects of a bold and contrasty character a very effective appearance. All five brands of paper were developed by the developer which we happened to have at hand at the moment, namely, amidol, and evidently call for no special treatment in order to produce the effects which we have attempted to describe. For specimen prints and samples of the paper, Messrs. B. J. Edwards and Co. should be written to direct.

**Wellington "Extra Speedy" Plates.** Made by Wellington and Ward, Elstree, Herts, England.

With their new plate of this designation Messrs. Wellington and Ward add a plate of extreme rapidity to their esteemed "Speedy" brands, and have produced, so far as our experience has gone, an emulsion of the brightest rapidity. Halation, that bugbear of photographers of the old days, is much less in evidence with the modern plates, and some exposures of figure studies silhouetted against a strong light which we made with the object of testing this point, proved to us the satisfactory quality of the "Extra Speedy" in this respect. For quick work in the studio, and for the many purposes of outdoor photography, where the shortest exposures have to be given, the new plate may take its place as among the best procurable. It develops quickly and without a sign of inherent fog, and gave us, with ordinary metol-hydroquinone development, a set of negatives of excellent range of gradation. It is a plate, in short, on which dependence may be placed in undertaking the most diverse descriptions of photography.

**The "Velbro" Bromide Paper.** Made by Elliott and Sons, Ltd., Barnet, Herts, England.

Of late, Messrs. Elliott, who were early in the field with a platinum-matt bromide paper, have given special attention to papers of distinct and useful surface, and their names for them have not over-described the characteristic effects obtained with the papers. Thus the "Tiger-Tongue," as a bromide paper, has given great satisfaction for enlargements on a fairly rough cream-tinted bromide, and has proved specially amenable to methods of sulphide toning. "Lustra" matt and "Oyster Shell" matt are other papers of peculiarly delicate and delightful surface, which have emanated from the Barnet factory. In "Velbro," Messrs. Elliott have given us a paper of semi-matt character (perhaps rather more glossy than matt), which they justifiably liken to a typical carbon print, and the comparison is one which the print will bear, not only on account of its fine velvety surface, but for its brilliance and great range of tones. "Velbro" we have found, in our experience of it, to give exceedingly brilliant prints with perfectly clean whites, and with a range of gradation in the shadows which has done full justice to negatives which on other papers would require considerable doctoring to secure their full quality. "Velbro," it need only be added, is issued in the same sizes and prices as the other papers of Messrs. Elliott.

**Satin "Zigas" (Gaslight) Paper.** Made by Thomas Illingworth and Co., Willesden Junction, London, England.

In issuing this new brand of their gaslight paper, Messrs. Illingworth have moved in the direction of recent popular preference for

a paper which is neither matt nor glossy, but something between the two, and a shade nearer glossy than matt. The prints on the Satin "Zigas" which we have made have shown us the pleasing character of the surface on which the not inappropriate title of "Satin" has been bestowed. The clean, brilliant prints given by the paper will gratify those who set especial store on this certainly essential quality in a gaslight paper. The "Satin Zigas," we can say, is a high quality of this modern description of printing paper.

**Criterion "Non-Stress" Bromide Paper.** Made by the Birmingham Photographic Co., Ltd., Stechford, Birmingham.

A "glossy" variety has long figured among the brands of bromide paper manufactured at the Criterion Works of the Birmingham Photographic Co. It is now issued under the title "Non-Stress," a revision made to indicate certain improvements of the manufacture, which remove from the paper any tendency to show the friction marks which are a not uncommon cause of annoyance to workers of glossy bromide papers. To what extent the Criterion glossy paper suffered in this respect prior to the change we cannot recollect, but we have the strongest grounds—those of practical tests—for declaring that the present manufacture does not belie its new designation of "Non-Stress." Apparently it is impossible to get it to show the stress or friction markings; at any rate we found it impossible to get them by rubbing the paper vigorously in contact with the negative, and, in addition, scoring the sensitive surface with the blunt end of a lead pencil. Markings were plainly visible on the paper before development, but none on the finished print. Such a test is unduly severe, and more than confirms the claims made by the maker. We need say no more, except that in other respects the paper is eminently satisfactory, of good vigour and colour, and pure in the whites, and that samples and prices are gladly sent by the company—particularly to workers abroad—on receipt of trade card.

**Wellington Portrait Carbon S.C.P.** Made by Wellington and Ward, Elstree, Herts, England.

"S.C.P.," it may be necessary to explain to some readers of the issue, stands for "Slow Contact Paper," and is Messrs. Wellington and Ward's designation of the paper of the gaslight variety manufactured by them. "S.C.P.," pure and simple, as first introduced, and still, of course, manufactured in six different grades, gives a particularly plucky print from a not particularly strong negative. Other varieties are made for softer effects, and to these has now been added a "Portrait carbon S.C.P.," which is a gaslight paper manufactured especially to yield the soft effects from negatives of average good vigour, such as a professional photographer will produce for printing in P.O.P. We therefore submitted the new paper to the test of printing from negatives of average portrait subjects, using for the purpose a developer of full strength which would, if anything, favour the production of harshness of contrast in the prints. The results, however, gratified us by their softness and retention of detail in the light tones of the subject, and it is evident that with correct exposure, an essential item in all gaslight printing, the "Portrait S.C.P." gives very fine results. Messrs. Wellington and Ward are too long experienced in the manufacture of printing papers, and are too jealous of a reputation which has been built up on this branch of the photographic materials trade, to lower in the slightest the standard of quality which they have set up and have caused to be recognised wherever "Wellington" products are employed. Hence it is almost superfluous to say that in point of cleanness of working, good colour, and beauty of surface the new paper is fit to rank with its fellows from the Elstree factory, and we can hardly bestow higher praise than that. The new paper is marketed at prices uniform with those of the other grades of S.C.P.

**"Studio" Zelvo Bromide Paper.** Made by Thomas Illingworth and Co., Willesden Junction, London, England.

The demand of late for bromide papers of semi-matt surface has evidently been an increasing one. The dead matt appears to have declined in favour, and photographers have shown a preference for a surface with a little sheen, the beneficial effect of which is seen more particularly in the shadows of the subject, which are relieved of the lifeless look which often is noticeable in a quite matt bromide print. The modern improvement in emulsions for bromide

is no doubt partly responsible for the difference, but the improvement is equally marked in the choice of surface obtainable in final print. Messrs. Illingworth, who of late have stepped to front with their bromide paper, have therefore done well in recognising the public demand and satisfying it with this new variety of their product, "Zelvo." The results obtained on it during the past few days have pleased us for their fine, semi-glossy surface, and for the pleasing softness of the prints. In this respect "Studio" Zelvo is perhaps more suitable for professional work than the usual Illingworth bromide, which gives slightly more contrast. Specimen prints made on the new paper, and, we may add, on the other silver papers and carbon tissues of Messrs. Illingworth, are sent on application.

**Scaloid Chemicals Tablets.** Made by Johnson and Sons, manufacturing Chemists, Ltd., 23, Cross Street, Finsbury, London, England.

Among materials to which we should not omit to draw the attention of photographic workers in distant parts of the world are the compressed developing and other tablets manufactured by the old firm of Johnson's in the City of London, and widely known and used by photographers in England. The necessity of purchasing chemicals needed for the photographic processes in such a way that the supply can be opened in small doses is less pressing in the case of the home user than it is in that of the photographer living far from sources of supply; yet even the former has recognised the advantage of using the fresh and active solutions which are obtained by employing the compressed tablet chemicals prepared from materials tested for purity by the experts of a manufacturing firm. Johnson's produces have, in our regular use of them, proved their accuracy of composition and photographic activity so fully that attention may be properly drawn to them for the benefit of obtaining their supplies of such materials—as they are almost entirely from the home country. The "Scaloids," as Messrs. Johnson's chemicals are termed, are put up in boxes containing, as a rule, twenty tablets of each of the (usually) two constituent chemicals of the formula. The whole box makes, in many cases,

of developer—that is to say, quantities of 2 oz. and upwards may be dispensed quickly and accurately simply by dissolving one or more of each of the two kinds of "Scaloid" in the box. The list of "Scaloids" obtainable includes developers such as amidol hydroxide, pyro-soda, pyro-metol, and glycin. It comprises also the intensifiers and reducers, the toning baths in customary use, even a complete set of chemicals for the Autochrome process. A booklet of instruction in the use of "Scaloids" gives much useful information, but perhaps the greatest obligation under the circumstances is due to Messrs. Johnson for the provision of the "Crushmeter," a 4-oz. measure of special shape and solid construction in which the tablets are almost instantly reduced to powder by the glass pestle provided for the purpose. No cleaner or more convenient way of making a solution exists, and the "Crushmeter" is a last appliance which we would part with from our dark-room, and useful do we find it on practically every occasion when almost

any kind of photographic work is being done. The price of this most handy appliance is 2s.

**Ilford Ivory P.O.P., Matt and Glossy.** Made by Ilford Limited, Ilford, London, England.

To the six well-known varieties of Ilford P.O.P. have just been added two others, to be known as "Ivory" matt and glossy, and each on a pale cream support which gives a most pleasing effect to the print, particularly in cases where the negative is harder than it need be for good P.O.P. printing. A cream glossy paper can easily be too pronounced in character, and the effect is then far from satisfactory, but the adjustment of the depth of tint in the case of the Ilford "Ivory" papers has been done to a nicety, and the harmonious results in both the matt and glossy paper are extremely good. Adopting the universally known procedure of sulphocyanide toning recommended by the makers, our results gratified us very much, and we are bound to suppose that the addition of the "Ivory" to the other brands of Ilford P.O.P. will be welcomed by many classes of users.

**XL "Kriso" Gaslight Paper and XL P.O.P.** Made by B. J. Edwards and Co., Castlebar Works, Ealing, London, England.

Further additions to the specialties of Messrs. B. J. Edwards are the above papers, the first of which, the "Kriso" gaslight paper, we have been very pleased with in making a number of prints on the "smooth" variety. Three brands of the paper are issued by the makers, namely, "smooth," "matt," and "regular grain," the first having an extremely fine surface of the semi-matt order with perhaps a shade less gloss than was possessed by the old albumen paper. The paper we find to give a very fine range of tones, beautiful clear lights and a fine black colour, and we judge from our trials of it that it is an excellent brand of the gaslight type of paper.

Of the P.O.P. it is sufficient for us to say that in the sulphocyanide gold bath it gives us tones of the warm purple characteristic of that method, and impresses us as being a sample of P.O.P. fully deserving to be ranked with the other Edwards' productions.

**"Kiplo" Self-Toning Paper.** Made by Elliott and Sons, Barnet, Herts, England.

The new self-toning paper just issued by Messrs. Elliott under this title is an advance on the paper of the same description previously manufactured by the Barnet firm in that the tone is obtained in a simple hypo bath of 2ozs. per pint, in which the prints are immersed direct for about ten minutes. A good warm brown tone is given by this procedure, or a somewhat colder tone is obtained by adding about 25 grains of sodium bicarbonate to the bath. The latter, we agree with Messrs. Elliott, is an improvement as regards permanency of the results, since the bicarbonate neutralises traces of acid carried into the hypo solution from the paper. It is all to the credit of the paper that it tones well in this carbonated bath. For more purplish tones a preliminary 5-minute 5 per cent. salt bath is used, and is followed—with a brief rinse between—by the fixing bath already mentioned. The paper is issued in both matt and glossy varieties, and, as proved to us by the prints we have made, gives very rich full-toned prints of very pleasing tone.

**Acid Diamidophenol Stand Developer.** Sold by F. C. Clarkson, Colchester, England.

We have received from Mr. Clarkson, of Colchester, a sample of acid diamidophenol prepared for tank development according to the following formula:—

Diamidophenol .....	10 grs.
Anhydrous soda sulphite .....	60 grs.
Liquid bisulphite (Clarkson's dye) ..	100 mms.
Pot. bromide, 10 per cent. solution ..	50 mms.
Water to .....	20 ounces.

A trial of this developer gave excellent results. The time of development was about thirty minutes, and the resulting negatives were perfectly clean and free from stains or markings. Mr. Clarkson will send a sample one-ounce bottle of his diamidophenol, post free, for 1s. 3d., or twelve one-ounce bottles for 10s. 6d. Those who have not yet tried diamidophenol as an all-round developer would be well advised to do so. The price is very low, while the developer is equally useful for negatives, slides, bromide, or gaslight prints.

**THE BARNET "STUDIO" PLATE.**—This new plate issued by Messrs. Elliott and Sons, Ltd., Barnet, Herts, England, specially for portrait

work, we have found to carry a liberal coating of emulsion, to give negatives of good vigour and detail in both high lights and shadows, and to permit of considerable latitude in exposure. The "Studio" is certainly a very rapid plate, yet free from fogging propensities.

**GRIFFIN'S "PROFESSIONAL" PLATE.**—In this new plate, supplied particularly for studio use, Messrs. John J. Griffin and Sons, Ltd., of Kingsway, London, England, offer an emulsion which, as we have found it, is very rapid, clean in working, and capable of giving portrait negatives of very fine quality. The plate supplies another instance of the care taken of the professional photographer nowadays by the manufacturers.

**THE "PROCEX" HALF-TONE PLATE.**—This plate, issued by the Halifax Photographic Co., Halifax, England, for the half-tone block-maker, has therefore been tested solely from this point of view, although we may add, for the benefit of the ordinary worker, that the results have shown it to be a plate giving a good clear line with a considerable intensity of deposit. So far as its speed is concerned, the plate works out to practically 60 H. and D. It was tested as to

its suitability for half-tone work by making a screen negative with 155 cross-line screen, which negative was then enlarged 30 diameters, and a photomicrograph, herewith reproduced, taken of the dot formation. It can be seen that the plate comes through this ordeal exceedingly well, and proves that it is capable of giving very sharp non-woolly dots even without any treatment in the way of intensification or reduction, neither of which were used in the test.

**PERMANENT SILVER PRINTS BY GASLIGHT.**—To the article in last week's "B.J." on the new "Synoloids" process, we may offer a word or two of explanation in reply to the inquiries asking for more information as to this innovation in silver printing. The paper is not yet on the market, but is promised to be ready in less than three months' time. The supply on which our remarks of last week were based is, we believe, the only paper yet placed at the disposal of the Press. As pointed out in the article, a latent image is obtained by a very brief exposure to artificial light, and on development in a weak acid developer (used in full working light) gives a silver print which can be made of cold or warm tone at will, and from its mode of production is certainly as permanent as a developed bromide or gaslight print, both of which, as is universally admitted, are to all intents and purposes permanent. The method permits a very thin coating of the paper without sacrificing richness of the prints, as the picture is built up from soluble or semi-soluble silver salts, and this, as we have proved for ourselves, without any staining of back or front of the prints. Hence fixing and washing are very short operations, and the whole process is one which is of particular interest to workers abroad, the makers having very fully tested the paper's keeping qualities in tropical climates. We understand that by the time letters from our colonial readers can reach the makers at 85, Gracechurch Street, London, England, they (the makers) will be ready to send samples and full working particulars.

**COLOURED POSTCARDS FROM PHOTOGRAPHERS' NEGATIVES.**—The London Studio, of 20 and 22, St. Bride Street, Ludgate Circus, London, E.C., send us some excellent and most attractive samples of postcards in colour, which they are offering to do for photographers in small quantities. They offer these cards at a price of 30s. per thousand from a single subject, or 1,000 each of twelve cards at a price of £17 8s. The best suggestion we can make is that those interested in cultivating this profitable side of photographic business should write to the London Studio, enclosing three penny stamps for their full tariff of prices and a sample set of both the coloured cards and the black and white work of which the London Studio has hitherto made quite a specialty.

**ZEISS TELEPHOTO CAMERA.**—A new camera has just been issued by Messrs. Carl Zeiss, 29, Margaret Street, London, England,

specially for telephoto work. It is fitted with a special rapid lens of 32in. focal length, the largest aperture being  $f/10$ . The camera is about 9in. long and 6in. to 7in. wide, and carries the Zeiss focal-plane shutter for instantaneous and time exposures. At present it is made only in one size, taking 9cm. by 12cm., or 4 $\frac{1}{2}$ in. by 3 $\frac{1}{2}$ in. plates. The lens is supplied in focussing mount, with the scale ranging from six yards to infinity, and a Zeiss monocular prism glass of a magnifying power of four is fitted as a finder. The price of the complete outfit is £45.

**PHOTOGRAPHS OF THE FAR EAST.**—A link between ourselves and our many friends throughout the Far East, into whose hands this issue will fall, is formed by the "Photographs of the 'Orient,'" by H. G. Ponting, F.R.G.S., now being held at the little gallery at the house of "The British Journal of Photography," near the Strand, London. The collection includes photographs taken in Japan, Burma, China, and India, and gives as vivid an impression of the scenes and characters to be met with in these countries as one can imagine photography capable of. The whole of the pictures, it may be added, are sulphide-toned bromide enlargements from the studios of the well-known firm of Raines and Co., and represent the high-water mark of commercial work. All Colonial readers who chance to be in London are asked to visit the offices of the "British Journal," where they will usually find an exhibition in some way or other representative of a modern aspect of photography.

**NIGHT PHOTOGRAPHY.**—Messrs. Dawbarn and Ward, Limited, 4, Farringdon Avenue, London, E.C., have issued a well-printed monograph on night photography, chiefly outdoors, by Mr. Robert Dykes, whose work in Edinburgh, London, and Paris with a camera by night represents a very high standard of this difficult branch of photography. The publication, which is at once an album and a text-book, is issued at 1s. net.

**THE TELEPHOTO QUARTERLY.**—We have to welcome into the ranks of photographic editors Captain Owen Wheeler, who has commenced the issue of a publication, the "Telephoto Quarterly." Under his quite personal editorship the "T.Q.," as our new friend is to be known, can hardly help being of vital practical interest to those engaged or interested in telephotography. All communications in reference to our new contemporary should be addressed to Captain Wheeler, "Strathmore," Princes Road, Weybridge, England. The price of an annual subscription, post free, for the "T.Q." is 1s. 6d.

#### CATALOGUES AND TRADE NOTICES.

**LANCASTER CAMERAS.**—A new catalogue from the Birmingham firm of J. Lancaster and Sons is a publication deserving of more than passing notice, coming, as it does, from a firm which for twenty years past has never abated its energy in anticipating the wants of the amateur photographer and in supplying him with apparatus suited to his requirements and moderately priced. Those who, like ourselves, commenced photography with a "Lancaster" camera, will peruse with interest this latest issue, wherein figure particularly a variety of reflex cameras, folding hand-stand cameras and a number of the convenient enlargers and enlarging illuminators which are a special department with Messrs. Lancaster. The list is sent free on application.

**HEINRICH ERNEMANN (ERNST HERBST AND FIRL), GOERLITZ, GERMANY.**—This is a well-got-up and interesting catalogue of fifty-seven pages in French and English. It includes a very large variety of the "Globus" cameras, from  $\frac{1}{4}$ -plate size up to the largest studio and process cameras. Some of the camera stands have novel and very useful features. We note one stand in particular that can be varied in height from eighteen to sixty-four inches, and is also adaptable for vertically photographing persons in a recumbent position. This stand, therefore, has special uses, both in the studio and in the hospital. A very special outfit is one designed for use in criminal identification photography. This includes a very peculiar and apparently uncomfortable type of chair that will only allow the sitter to assume one position. This particular kind of work is, of course, quite outside ordinary professional photography, but it is worth mention as an example of the completeness of the catalogue.

# Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, MARCH 27.

Week Photographic Society. Rotary Specialties.  
Cardiff Photographic Society. "In Northern Brittany." A. E. Harris.

SATURDAY, MARCH 28.

Liverpool Amateur Photographic Association. Excursion to Bidston.

MONDAY, MARCH 30.

Levensham Camera Club. "Hand Camera Work with a Vindex." W. G. Hill.  
Scarborough and District Photographic Society. "Miscellaneous."  
Bradford Photographic Society. "Pin-hole Photography." J. R. Coulson.  
Alderminster and District Photographic Society. "Flower Photography."  
W. W. Baker.  
Lancaster Photographic Society. Lantern-Slide Competition.  
Stercliffe Photographic Society. Rotary Carbohydrate Paper.

TUESDAY, MARCH 31.

Royal Photographic Society. "The Camera as an Aid to the Study of Birds."  
W. Bickerton.  
Lancaster and District Literary and Scientific Society. "Gaslight Paper." Mr.  
Edwards Photographic Society. Rotary Carbohydrate Paper.  
Huddersfield and District Camera Club. "Oil Printing." Demonstrated. T. Haldane  
Harrison.

WEDNESDAY, APRIL 1.

South Suburban Photographic Society. "Colour Photography (including Develop-  
ment of Autochrome Plate)." A. W. M. Dickens.  
Leeds Camera Club. "Theory and Practice of Time Development." W. F.  
Slater, F.R.P.S.  
Leydon Camera Club. Annual Rummage Sale.  
Barnford Photographic Society. "In Italy with a Hand Camera." F. G. New-  
march.  
Rough Polytechnic Photographic Society. "Three Colour Photo-Micrography."  
Dr. A. Norman.  
Leventry Photographic Club. Annual Meeting.  
Inverburgh Photographic Society. "Some Things About Brittany." Charles  
Stol Photographic Club. A Special Evening for Elementary Workers.  
United Stereoscopic Society. "Some Crude Attempts at Hand-drawn Stereo-  
graphs." P. Snow.  
Crystal Photographic Society. Rotary Carbohydrate Paper.

THURSDAY, APRIL 2.

Leley, Farsley and Calverley District Photographic Society. Kodak Lecture.  
Mr. Slater.  
Liverpool Amateur Photographic Association. "Studies from Life of Reptiles  
and Amphibia." Dr. John H. O'Connell.  
Aldridge Wells Amateur Photographic Association. "Switzerland, the Beaten  
Track." W. J. Mackie.  
Allothian Photographic Association. "Some Fundamental Principles of Pic-  
torial Photography." Jas. Patrick.  
Hemelton and District Camera Club. "The Camera as Historian, County  
Record Work." The Photographic Survey and Record of Surrey.  
Photographic Society. Annual General Meeting.  
Gly Photographic Society. Annual General Meeting.  
Letchworth-on-Sea Photographic Society. "Printing and Toning." Miss Florence  
Bell.  
Leeds Camera Club. Club Lantern Slides 1907-8.  
London and Provincial Photographic Association. "The Nature of Colour." Dr.  
C. E. Kenneth Mees.  
Lancaster Photographic Society. "Photographic News Prize Slides."  
Leeds Photographic Society. "A Trip to Morocco." H. Lambert.  
Hemond Camera Club. Lantern Evening.  
Leley and Worsley Photographic Society. Rotary Carbohydrate Paper.

## ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held March 24. Mr. A. J. Newton read a paper on "Three-  
colour Work." He regretted that he had nothing startlingly new.  
The theory of three-colour was really extremely simple, and pro-  
bably familiar to those present. Nevertheless, they perhaps had  
seen a demonstration of the facts upon which it was based, and  
they had at the L.C.C. School of Photo-Engraving worked out a  
very simple manner of making this demonstration, he proposed to  
do it before them to-night.

The lecturer then dealt with the nature of light and colour, point-  
ing out that colour was a purely subjective phenomenon, and that  
it arose from absorptions of some of the constituents of white light  
falling upon the objects. This was proved by first of all projecting  
the spectrum and then placing in its path various coloured substances.  
The point was that imitation of all colours could be obtained  
by mixtures of three. Three portions of the spectrum were isolated,  
projected on the screen, and blended in various proportions to  
obtain all sorts of colours.

The application of this fact to photography was then fully  
described, and various one-plate processes were shown to depend  
on his addition of three-coloured lights. After this the subtrac-

tive processes for three-colour photo-mechanical illustration were  
dealt with, the latest devices in this respect being touched upon,  
as, for example, the use of coloured carbons and the use of non-  
filter collodion emulsions. In regard to this latter, some striking  
examples were exhibited, showing that, so far, results could not be  
obtained in any way to approach those produced with colour filters.

The lecture was illustrated by numerous examples of three- and  
four-colour illustrations lent by some of the leading firms, showing  
the great perfection to which the process had now attained.

## Commercial & Legal Intelligence.

BRITISH PHOTO PAPER COMPANY, LTD., LONDON.—Issue on Feb-  
ruary 24 of £125-6 per cent. debentures, part of series created Novem-  
ber 6, 1907, to secure £5,000, charged to the company's undertaking  
and property, present and future, including uncalled capital. No  
trustees. Total amount previously issued of same series, £3,340.

ANOTHER ENLARGEMENT CASE.—At the Scarborough County Court,  
before his Honour Judge Cyril Dodd, Harriet Kemp, widow, Scar-  
borough, sued the Great Britain Art Company, Manchester, to  
recover money paid to the use of the plaintiff, two photographs  
detained, and for damages for non-delivery of a framed enlargement,  
and for detaining the two photographs. Mr. John Whitfield appeared  
for the plaintiff, and the case was undefended.

Mr. Whitfield stated that in October, 1906, a lady called on the  
plaintiff, who arranged to have a photograph of her deceased husband  
enlarged. The price was to be 18s. 6d., payment to be made by  
instalments, and after all these were met the photograph was to be  
delivered.

The plaintiff, in the course of her evidence, said the defendants  
had not delivered the enlargement, nor had they returned the two  
photographs of her deceased husband that she handed over. She  
had written and received no reply. Witness had paid 19s. in instal-  
ments.

His Honour: There will be judgment for £6 and costs, execution  
to issue within a week unless the two photographs be returned. In  
that event judgment will be for the plaintiff for £1 and costs. If,  
added his Honour, defendants came into Court before he rose he  
would allow them a new trial on payment of the debt and costs  
into Court.

Subsequently a young man entered the Court, and, stating that  
he represented defendants, asked for the case to be reopened.—His  
Honour: Have you got £6 with you?—Applicant: I have about  
£3.—If you pay into Court £6 I will re-hear the case. The Great  
Britain Art Company ought to be able to raise £3 in the course  
of the day.—Applicant: I shall have to wire for it.

The applicant then left, and up to the rising of the Court had  
not reappeared.

LUTON BANKRUPTCY.—A receiving order in bankruptcy has been  
made against Arthur Joseph Anderson, photographer, etc., 37,  
Wellington Street, and 36, High Town Road, Luton, and 7, High  
Street, Leighton Buzzard, Bedfordshire.

LEGAL NOTICES.—Notice is given of the release of the trustee in  
the bankrupt estate of Francis Edwin Ellis, photographic artist, of  
Ivycroft, Stockfield Road, Streatham, S.W.

The partnership between Henry Vassar Lawley and Percival Edwin  
Stow, cinematographers, of Clarendon Road, Croydon, Surrey, trading  
as The Clarendon Film Company, has been dissolved by mutual con-  
sent. All debts will be received or paid by P. E. Stow.

PHOTOGRAPHIC APPARATUS FOR BOROUGH ENGINEERS. — The  
Borough Engineer of West Ham recently reported to the Council  
that it was desirable to purchase a camera for the purpose of obtain-  
ing photographic records of irregular buildings and other works  
coming under the supervision of his department. At the last meeting  
of the Council the Works Committee notified that they had authorised  
the engineer to obtain the necessary apparatus and equipment at  
a cost of £20.

## News and Notes.

**NOTICE.**—Owing to great demands upon our (enlarged) space this week an article on "Carbon Printing in the Tropics," intended specially for this "Colonial" number has had to be held over, with many notes and paragraphs, until next week.

**COLOUR PHOTOGRAPHY.**—The first issue of the "B.J." in every month is enlarged to find space for extra pages recording the progress in colour photography. This so-called "Colour Photography" Supplement serves the purpose of a separate publication in this important branch of photography.

**SINOP.**—The Sinop Collographie Co., of 40, Rue de l'Université, Reims, have appointed Mr. S. G. Yerbury, who is well known in collotype circles, to demonstrate their simplified form of collotype before societies. Secretaries are asked to kindly write for dates. This process is interesting, as it enables photographs to be printed in almost any paper and in any colour. Mr. Yerbury's address is 26, Milton Road, Acton, London, W.

**NEW OPENING FOR PHOTOGRAPHERS.**—Anyone visiting the commercial quarter of Paris (writes the "Globe") will have been struck by the extraordinary number of photographic cameras set up on the pavement about mid-day. Some enterprising photographers, it appears, have conceived the idea of photographing the city workers in groups, between the time they leave the restaurant and return to their work. By the following morning these portrait groups have taken the form of picture postcards, and are sold to the workers at a moderate price. The idea has "caught on" tremendously among the Parisian workers, who hastily devour their frugal mid-day meal to group themselves before the photographic lens, and these improvised "sittings" in the open lend a picturesque touch to the moving panorama of the streets.

**PHOTOGRAPHY IN THE TROPICS.**—Dr. Tempest Anderson, at the Yorkshire Philosophical Society last week, dealt with some points of importance to the tourist and worker in foreign countries: The choice of suitable plates; the extremes of damp and heat in the tropics playing havoc with certain makes of dry plates much more than with others; the best methods of keeping both cameras and plates quite dry, by means of ingenious chambers attached to the plate and camera boxes, designed to hold drying pads charged with chloride of calcium. Another thing that had to be guarded against was, a certain amount of radio activity which, at tropical temperatures, seemed to reside in the wood and aluminium which were so often used for dark slides and plate-holders. This led to the gradual fogging of the plates, beginning at the edges and creeping inwards. Much valuable advice was given as to the lengths of the exposures required under a tropical sun, which was generally very glaring and untempered by such strong sky light, such as generally prevails in this country. The result was that tropical shadows were relatively very dark, and therefore exposures, if intended to render details in the shadows, must be longer than the uninitiated would at first suppose. The lecturer showed a most ingenious contrivance for ensuring correct exposures, in the shape of plates cut into narrow strips and placed one by one in the camera for trial exposures. After exposure the strip is then introduced into a dark bottle of developer for 30 seconds without once seeing the light, and then taken out for momentary examination in the light, when the correctness of its exposure in the camera can at once be judged by the state of the developed image.

**PRINTS ON SALTED PAPER.**—Among the many formulæ used in the preparation of salted papers (writes Mr. W. A. McLean in "Focus"), the following I find most sure in working. The No. 1 or salting bath is:—

Common salt (sodium chloride).....	160 grs.
Ammonium chloride .....	80 grs.
Bichromate potassium (5 per cent. sol.).....	$\frac{1}{2}$ dr.
Gelatine .....	25 grs.
Water (distilled).....	20 ozs.

The gelatine must be cut into shreds with a pair of scissors; place the shreds into 25 ounces of distilled water, and boil in a clean enamelled pan, or in an earthenware jar placed in a saucepan of water; continue to boil until the 25 ounces of water boil down to 20 ounces, then add the bichromate, etc. Immerse the paper until limp and thoroughly saturated; naturally a paper soft and porous in quality

will not take nearly so long to become saturated as a fine-grained hard paper does, so that it is useless to state any definite length of time for immersion in this bath. The salted paper is dried and sensitised by immersion in:—

Nitrate of silver.....	1 oz.
Distilled water .....	9 oz.

**ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.**—The following have been elected members of the Selecting and Hanging Committees: Pictorial section—Messrs. W. R. Bland, Chas. F. Inston, E. T. Holding, Furley Lewis, J. C. S. Mummery, G. A. Storey, A.R.A., B. Gay Wilkinson. Technical section—Messrs. Conrad Beck, C. P. Butler, Douglas English; A. J. Newton, C. E. K. Mees, D.Sc., J. Sinclair, E. J. Wall, Major-General J. Waterhouse, I.A.

**SKYSCRAPER PHOTOGRAPHY.**—To crawl along one side of an X formed by the cross girders of the tower of a great bridge; to zigzag in this fashion up to a height of nearly 350ft., and then to stand on a little platform of steel less than 12ft. square, with no guard rail to keep you from plunging through to the surface of Blackwells Island, that is all in the day's work with a newspaper photographer. To walk across a bolt-studded strip of steel only 6ft. wide to another little platform, stopping half-way to focus on a group of workmen and take their picture, that is just a part of the every-day game with us (writes Charles Duprez in the "Camera"). After sitting on a girder extending from the thirty-seventh floor of the Singer Building and making a photograph of Broadway, a sheer 500ft. below, climbing the tower of the Blackwells Island Bridge did not seem much of a "stunt" to me. After I was at the top and hoisted my camera up by a rope it was exhilarating to get the splendid view of New York City and the sweep of East River north and south, and to look on the men in striped clothing working on the island below, not much bigger than flies to my eye. One false step and I'd have been down among them. But I would not have known I was there.

### FORTHCOMING EXHIBITIONS.

- March 21 to 28.—Midlothian Photographic Association. Sec., Robert Oliver, 6, Murieston Terrace, Edinburgh.  
 March 27 to 28.—Catford and Forest Hill Photographic Society. Sec., T. Browne, 169, Woolstone Road, Forest Hill.  
 March 30 to April 4.—Malvern Camera Club. Sec., J. B. Nickolls, The Exchange, Malvern.  
 March 31 to April 4.—Sheffield Photographic Society. Hon. Sec., J. W. Wright, 62, Vale Road, Sheffield.  
 April 21 to 24.—Southend-on-Sea Photographic Society. Entries close April 6. Sec., J. Archer, 24, Ashburnham Road, Southend-on-Sea.  
 April 22 to 25.—Plymouth Photographic Society. Entries close April 14. Sec., Wilfred Grist, The Athenæum, Plymouth.

## Correspondence.

- \* We do not undertake responsibility for the opinions expressed by our correspondents.
- \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

### THE R.P.S. SELECTION COMMITTEE.

To the Editors.

Gentlemen,—The Journal of the R.P.S. issued to-day, referring to my proposal that the Selection Committee of the Pictorial Section of its exhibition should each year include two new experts, states that "the recommendation was lost . . . neither mover nor seconder voting in its favour." As this may lead some people to think that I, being satisfied with Mr. Wall's hope that the same lot "would be appointed for many years," or with the president's opinion that it was best "to let it alone," tacitly withdrew my contentions, permit me to state that the discussion only confirmed me in the opinion that in this matter the council has lost touch with the spirit of progressive portraiture, and that the practice of appointing the same six

en year after year to be sole arbiters of which is pictorially noteworthy is from every point of view indefensible.

Although the annual meeting (which it should be observed was most entirely confined to members of the council and officers of the society, supported by a sprinkling of plate-makers and wasters) the one voice rejected my motion, it has apparently borne fruit, for though at the time the President refused to pledge the council, the latter has since so far adopted my view as to place two new men on the Selection Committee for 1908. During the past few days I have received many expressions of approval of my action, including a very strongly-worded letter from an exceptionally prominent exhibitor, from which I am inclined to think that three-fourths of the exhibitors are outside the charmed circle will be with me in this matter. It is specially desirable that provincial exhibitors should speak out promptly and raise their voices against a monopoly which spells monotony, and which is also calculated to bear very heavily on those who, living at a distance from London, have few or no opportunities of appealing from the verdict of a permanent Selection Committee. The mere fact that the composition of the committee is changed every year is sufficient to make the candidate for pictorial honours hope that eventually his efforts will receive recognition.—

Faithfully yours,  
Cheam Road, Sutton,  
March 21, 1908.

HECTOR MACLEAN.

#### THE PORTRAIT POSTCARD.

To the Editors.

Gentlemen,—May I beg a small part of your valuable space to ask guidance from yourself, or from some of your professional or manufacturing readers? The portrait postcard is here! It permeates the idea of the public. It is very cheap, and often very good. The middle-class and upper middle-class public ask for it. Their idea of its value is from one penny to twopence each. However, they are willing to strain a point and to order a dozen at 6d. as an outside price, but they want proofs. Pretty and effective mounts (oblong and upright) and frames can be had for a copper too each. The effect then is that of high-class cabinet work. A comrade of mine who has hitherto always had cabinet work, brought my studio four children and a dog, and said she required four different pictures, viz., four children and dog, one child and dog, children alone, four children alone. A number of plates were exposed and good results obtained in each case. The lady then she would have postcards, at which announcement I felt myself a bit puzzled. We were paid 10s. for four dozen postcards, and proofs were sent for. The lady told me to-day she was quite delighted with the postcards, and that she thought them quite equal to cabinets. Several of this lady's friends have ordered postcards. A week's work went into 30s. My expenses are: Wages, rent, materials, etc., 15s. Had this twelve dozen postcards been cabinets I should have received almost £7. Now, for a great number of years, the cabinet portrait—silver, platinum, or carbon—has been the mainstay of the manufacturer and of the professional man, but the postcard now comes, and it is going to ruin and bring into contempt and commercial prostitution both the manufacturer and the portraitist. I think I have evidence that the manufacturer is beginning to feel the draught, because no less than seven travellers, from firms of plate and paper makers who have never called on me before, have been in my studio since January 1.

Now, Sir, will you be so good as to advise the proprietor of a small cabinet business what is his practicable attitude towards the portrait postcard?—Yours faithfully,

POSTCARD.

While we deplore, as much as anybody, the changed condition of things, we must point out to our correspondent that his practice in giving sittings ad libitum without an understanding as to the sitter's price is unbusinesslike. We are afraid there is no easy remedy. Photographers have been confronted with the same difficulty "Postcard," and have either declined to take orders for such work, or have run strong on it and made money. One recommendation that has been made is to the effect that a portrait to be printed on a card should be taken, of about carte size or a quarter-plate, and covered with a mask on the postcards, but such a measure is obviously useless in the face of competition with postcard portraits the size of the card.—Eds., B.J.]

Coming to our going to press earlier than usual several letters are over.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

#### PHOTOGRAPHS REGISTERED:—

- A. Paterson, 19, Academy Street, Inverness. Photograph of the Rev. A. Bremner
- J. A. Povah, 9, Rosthwaite Road, West Derby, Liverpool. Photograph of a Coasting Schooner homeward bound off Northumberland Coast. Photograph of the Launch of the "Mauretania," September 20, 1906. Photograph, Salting and Packing Herrings for Conveyance by Rail at the Fish Quay, North Shields. Photograph, Schooner in Full Sail. A Breezy Day of the Tyne.
- W. G. Fudger, Rosedale Studio, Peperharow Road, Godalming, Surrey. Photograph of the Interior of the Congregational School, Godalming. Photograph of Congregational Church (Interior), Godalming.
- C. E. Field, the Waveney Publishing Company, High Street, Yoxford, Suffolk. Photograph, Baptism of a Female Candidate by the "No Sect" Preachers on Middleton Moor, Suffolk.
- G. Laurens, The Parade, Station Road, Wealdstone, Harrow. Photograph (Flashlight), Group of Wealdstone and District Parliament.
- E. A. PEEPLES (Mulgrave, Nova Scotia).—The L.C.C. School of Photo-Engraving and Lithography, 6, Bolt Court, Fleet Street, London, E.C.
- W. H. THOMPSON (Hartford, Conn.).—One glass only. If two glasses are cemented with coloured gelatine on both, then half that quantity on each. We coat one glass only, and cement a piece of glass on top.
- R. K. BONINE (Honolulu, Hawaii).—I should like to obtain some information on the subject of making bromide of silver emulsion, and the method of coating same upon glass and film. Can you refer me to any publications on this subject, or any serial articles that have appeared in the photographic magazines?  
You will find some very useful general information in Sir William Abney's "Photography with Emulsions" and his "Instruction in Photography," and also in Eder's "Handbuch" (Part III.). Modern methods practised by plate makers of course involve trade secrets that are not published.
- S. C. BONNERJI.—For the lens, J. H. Dallmeyer, Ltd., or Carl Zeiss; for the shutter try Newman and Guardia or Adams and Co., although we think there must be some misunderstanding as to the firm you mention declining to fit their new model.
- WILFRED.—"Kinematograph and Lantern Weekly," E. T. Heron and Co., 9-11, Tottenham Street, W.
- LITHO.—Photo-litho paper is a hard paper coated with gelatine. It is sensitised with a solution of bichromate of potash and then printed. It is then inked up with litho transfer ink, and the image afterwards transferred to a lithographic stone and printed from in the usual way of lithography. The paper is supplied by Messrs. Penrose and Co., Farringdon Road, and others. If you desire full working instructions of the process you cannot do better than get "Photo-lithography," by Geo. Fritz (Dawbarn and Ward, Farringdon Avenue, E.C., 3s. 6d.).

HARRISON and EVANS, and others.—In our next.

A. SMITH.—See the "Almanac," 1908, page 947, under "Combining

Lenses," in which formula read  $F$ ,  $3\frac{1}{2}$  inches  $f/1$ ,  $6\frac{1}{2}$  inches, and  $f/2$  the focus of extra lens.

W. BUSHELL.—"Der Photograph," c/o Benno Fernbach, Bungalow, Germany; "Die Photographische Industrie," Dresden, A21, Germany.

W. STORRIE.—Wyndham and Co., collotype printers, Acton, W., or perhaps Harold Hood, Ltd., St. Bride Works, Middlesbrough.

CATHAY.—See review in this issue. 2. To the enlargement if an unsymmetrical lens is used. If symmetrical, the position does not matter.

B. B.—We can only refer you to the usual sources of information—the directories, and the lists of members that some societies issue.

A. MOORE (Ramsey).—Cassella and Co., Frankfort-on-Maine (Agents, Pronk, Davis and Co., 22, Harp Lane, E.C.); Actien-Gesellschaft für Anilin Fabrikation, Berlin, and 20, Eastcheap, London E.C.; Badische Company, Ltd., 22, Bush Lane, E.C. (Badische Anilin and Soda Fabrik, Ludwigshofen a/Rh.); Chemische Fabriken vorm Weiler-der-Meer, Verdingen a/Rh.; Kalle and Co., Biebrich a/Rh.; R. Geigy and Co., Bâle, Switzerland; Chemische Fabrik Sandaz, Bâle; Society of Chemical Industry, Bale; Bale Chemical Works, Bale.

COLLOTYPE.—Your help in the following will be thankfully received. I have been trying my hand with the collotype process on a small scale—half-plate. In my initial experiments I have not thought it necessary to go to the expense of a proper drying-box. But I have dried the plates in absolute darkness, and away from gas fumes or other injurious vapours. The plates dried in eight or ten hours, and looked very good. After printing, they were washed till they were free from the bichromate and dried. They were then heated with water and glycerine, according to the text-books, and the surface moisture removed. On trying to ink upon the plates the ink took evenly all over, and nothing that I could do with any of them improved matters at all. Can you tell me what is wrong?—V. C. RICHARDS.

Where you have gone wrong is in the drying, supposing you worked strictly by the text-books in the other details. One of the greatest essentials in the collotype process is the quick drying of the plates, and the temperature at which it is done. Owing to the long time your plates took to dry, the gelatine film had become so hardened that it would not absorb the water, and, consequently, they took the ink all over, instead of in proportion to the light's action. A proper drying box is one of the principal essentials to the working of the process. The time occupied in drying collotype plates is from three to five hours, and the latter time should not be exceeded.

CARBON TRANSPARENCY TROUBLE.—Will you please give me some help on the undermentioned trouble? I have been making some lantern slides by the carbon method, but when they are dry they all seem covered with a fine network, which shows very strongly on the screen. The plates were coated with the substratum, as given in the Autotype Company's book, and were dried in a room well lighted with gas, as the directions say "dry in the light." Can you explain the cause of the trouble?—J. A. BOWDEN.

The defect is what is known in carbon printing as reticulation. It may be due to several causes—such as too soft a substratum, the use of too hot water in the development, or to the tissue being too quickly dried, so that it is in a very soluble condition. Another cause may be that the tissue was soaked too long before it was squeegeed upon the glass. When pictures are developed on glass the tissue should not be soaked quite so long as when it is to be developed on paper. However, we have little doubt that your trouble is due to the first-named cause—the substratum not hard enough. The substratum should be exposed to strong daylight, which renders the gelatine thoroughly insoluble. Exposure to gaslight is not enough, hence substratum has been affected by the warm water in the development, and consequently reticulated. If this is the cause, and in all probability it is, the remedy is obvious—expose the bichromated substratum to strong daylight for a few hours. It is a good plan, and one followed by many who make carbon transparencies for enlarging from, to coat the tissue, after exposure, with plain collodion and allow it to dry before squeegeeing it on the glass. In this way all risk of reticulation is avoided.

## TO READERS IN THE COLONIES AND FOREIGN COUNTRIES.

We must point out to the many readers who make their first acquaintance with the "B.J." through the present issue, that we have been compelled to make considerable departures from our usual custom in issuing the present number, enlarged though it is. The photographic season is just opening here in England, and the result is that the number of new goods to reach our office for review is unusually great; yet we hope that the record of our experience in testing lenses, plates, and printing papers will be as valuable to our foreign readers as other matter which would occupy the same space, therefore we can do no harm in saying what sort of a paper the "B.J." is, and assisting the reader to decide whether it is worth while spending 13s. on the fifty-two numbers in the yearly volume. If our reader looks for reproductions of the modern so-called pictorial photography, or for oft-repeated instruction in most elementary processes, then decidedly the "B.J." is not for him. The space at our disposal is too badly wanted for more important matters. We make a point of giving the news of the trade and the profession, of dealing with the money-making side of photography, and of investigating quickly the new departures in any branch of camera work which appears of industrial or scientific interest. The "Correspondence" columns of the "B.J." provide every week some of the most interesting reading in the paper—sidelights on trade methods, experiences of practical photographers—and forms means of communication between distant workers which is open to all without fear or favour.

Scarcely less in interest are the "Answers to Correspondents," which are given by one or other of the staff of the "B.J.," or are obtained, if needed, from outside experts—a much appreciated feature of the journal, so we are led to believe.

Of our comments each week under "Ex Cathedra," and of our determination to be as soon as any other journal—if possible, a little sooner—with news of photographic progress, it behoves us to say little, but to let our readers judge for themselves from the journal.

These features may not impress the reader as intensely novel, but their solid value to the photographer at home and abroad has been attested over and over again by readers who have grown to old age during the fifty-four years throughout which the "B.J." has regularly appeared.

So far as individual help can be rendered to readers at a distance, those in the colonies and in foreign countries receive special attention. Questions on business and technical matters will be gladly answered, and the means of obtaining information which a newspaper offices of all places possesses is cheerfully applied for the benefit of our friends beyond the seas.

**\* \* \* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Modern Studio. The second chapter of Mr. Butt's article on the equipment of photographic premises deals chiefly with the question of external decoration. (P. 263.)

Professor Lippmann writes from the Sorbonne in further explanation of his new method of stereoscopic photography. (P. 273.)  
Amateur Photographer" of Tuesday last gives some further detail and suggestive details as to the new method. (P. 269.)

W. J. Russell, F.R.S., writes a letter of caution in reference to the action of substances upon the photographic plate on proximity or contact with the latter in the dark. (P. 274.)  
Portrait Postcard. Several correspondents give their experience in meeting this form of competition. (P. 274.)

On severe sentences on bogus photographers were passed last week and are reported in "Commercial and Legal Intelligence." (P. 271.)

Continuing the "Conversations on Copyright," we conclude this week the section dealing with the ownership of copyright. (P. 265.)

We regret to announce the death of Mr. A. S. Spratt. (P. 267.)  
Collection of the late Mr. Horsley Hinton's pictures will be on view at the R.P.S. from Wednesday next, April 8.

Regarding cameras, cinematograph mechanism and the telegraphic transmission of photographs appear among patents of the week. (P. 277.)

## "COLOUR PHOTOGRAPHY" SUPPLEMENT.

W. Scheffer, of the Carl Zeiss scientific staff, has published results in the microscopic examination of sections of the Autochrome film. (P. 25.)

French writer suggests and recommends a portable photographic means of ensuring correct exposure of Autochrome plates. (P. 26.)

On washing of Autochrome plates and their development with amidol figure in correspondence on colour photography. (P. 27.)

On von Hübl, whose book on the Autochrome process has been published (page 32), has given particulars of the sensitisation of the Autochrome plate as he has found it. (P. 30.)

German writer has thought well to give directions for the making of a single Autochrome transparency from a set of three-colour negatives. (P. 30.)

E. J. Wall, F.R.P.S., gives particulars of a green-light carbide lamp for illumination for three-colour work. (P. 28.)

Use of an after-bath of alcohol in the colour-sensitising of dry plates by bathing is recommended by Herr Paul Thieme. (P. 29.)  
Sensitising measurements of some new dye-sensitisers are given on page 31.

## EX CATHEDRA.

### Mr. Hinton's Pictures at the R.P.S.

The current issue of the "Photographic Journal" announces that a collection of photographs by the late Mr. A. Horsley

Hinton will be on view at the R.P.S. House, 66, Russell Square, W.C., from April 8 to May 5. The opportunity of seeing this collection should not be missed, for, while so many examples of Mr. Hinton's work have seldom or never before been seen together at one time, there is also a possibility that a similar collection may not readily be got together again. Mr. Hinton has been a great power in the world of pictorial photography, and it is only fitting that such an exhibition should be held at the earliest opportunity.

\* \* \*

### An Imperial Issue.

We have to thank those who have congratulated us on the reception accorded to last week's "Colonial Number" of the "British Journal," an issue which has now been despatched to photographers and photographic dealers in every quarter of the world. We are glad to find that our proposition to bring ourselves and others into touch with the large numbers of the photographic fraternity scattered in isolated places has been approved by the photographic trade as an eminently sound business proposition. We had to bide our time until we could talk of our ability to post a large extra edition to photographers not at present known to be on our books, but the labours of months having come to an end, we can now pride ourselves on being the possessors of a list of colonials and foreigners outside of Europe which we have reason to think represents a larger circle of buyers than any other list available for circularising purposes. As one reader puts it, the "B.J. Colonial Number" should be another link in the imperial chain of British commerce.

\* \* \*

### Lens-Testing at the National Physical Laboratory.

The report for the year 1907 of the National Physical Observatory shows a marked increase in the number of photographic lenses tested. In 1905 only eight were tested, in 1906 the number increased to eighteen, and in 1907 to twenty-nine. This is far more satisfactory, considering the number of new lenses that are issued every year, and it shows that makers are becoming convinced of the value of a "Kew" certificate as an advertisement of their productions. The twenty-nine lenses included one lens of 6 ft. focal length and of 5½ in. diameter, fitted with a prism and designed for the reproduction of plans in the Ordnance Survey Department, and also several process lenses. The advent of these latter has necessitated a modification of the testing apparatus, and by mounting the object and the observing microscope

on two parallel optical benches set at right angles to the axis of the lens, the process lenses are tested for their ability of producing a plane image from a near plane object, which is essentially the work they are required to perform. A new method for testing the definition of lenses has also been worked out by Mr. Hunter from an idea suggested by Major Leonard Darwin. Particulars of this method and of the apparatus used will be published shortly. This report shows that the Observatory is giving every attention to the testing of photographic lenses, and in view of this fact the value of a Kew certificate cannot be doubted.

### Evening or Morning Dress.

The experiment tried by the North Middlesex Photographic Society recently appears to have fulfilled expectations. There are, no doubt, many members of photographic clubs who do not avail themselves of the "claw-hammer" coat, having no use for it beyond two or three occasions in one year. These worthies rather naturally shrink from appearing in an assembly where all others, even the waiters, are as like as peas. It is a laudable reticence, and without doubt must often have kept dinner subscriptions much below a profitable number. On Saturday, the 21st, at the Hotel Florence, there was not only a larger gathering than formerly, but a cosy Bohemianism over all that was distinctly cheering. When such exalted people as the members of the Omar Khayyam Club have their dinners in morning dress, there can be no room for ideas of lowering the tone of a society when a similar free-and-easy course is adopted.

## PHOTOGRAPHERS' SHELIVING.

### II.

In the printing-room especially everything should have a place, and be kept there. Carpenters say that a clear bench means a saving in time of quite ten per cent., and the same is true of a printing-room.

Negatives should not be allowed to litter up the bench, but should have their proper shelves, with divisions for finished but unpacked orders, proofs, and specimens. It will be found advisable to classify the latter—say, under the headings of men, women, and children. There should

Fig. 1.

be places for tissue paper, stamp board and brush, vignettes, cover glasses, safe edges, stamp edging, and spotting colour and brush.

The pads and blocks of various sizes must be within reach of the bench where the frames are refilled. A handy shelf is made by taking two boards, eight inches by half-inch (Fig. 1), separating them by nailing between them several pieces of three inches by three-quarter inch stuff eight inches long. These short pieces are placed on edge, and

of sufficient distance apart to make suitable compartments of 1-1 plate pads, cloth, and rubber, blocks for blocking out half a whole-plate when two cabinets are taken upon half-plate pads and blocks, and quarter-plates. Any room over will be useful for odds and ends. By this method the top shelf is free for other work. If one has already a shelf in position, one has only to fit the divisions on board to have another free shelf immediately.

Masks of various shapes are always wanted, are always getting torn, and always difficult to get the right size. They are laid on an ordinary shelf. Pigeon-holes are not satisfactory for these, a miniature chest of drawers the

Fig. 2.

will stand on the bench is better. The different sizes and varieties have each their own drawer.

Dry-mounting on papers usually means a large variety of colours and sizes in mounts and tints. If the latter are piled together promiscuously it seems a small matter to get the required tint; but it will be found that if each is kept separately, yet within easy reach of the mounting table, the time saved is very appreciable.

For this purpose it is not a bad plan to provide a set of pigeon-holes, each hole being, in the case of the mounts, four inches deep, ten inches from back to front, and half an inch wider than the mount for which the particular holes are required. The best method of construction since there is but little weight to carry, is that shown in Fig. 2. As an example of the small space taken up, one may say that a set of holes to take twenty-seven varieties of mounts size 12 x 10, and an equal number size 10 x 8, only occupy a space 5 ft. x 3 ft. x 10 in. A similar set of holes for tints will take up much less room than that, five inches deep, three inches high, and ten or five inches wide being sufficient for each hole. To return to Fig. 2, this construction is not so difficult as it looks, since, after being

Fig. 3.

planed up and cut approximately to size, the upright and cross pieces respectively are nailed together, the two solid blocks then being trimmed up. The gaps are marked out to size with a square and gauge, sawn half through, and the piece removed with chisel. The pieces are then separated and slipped together, and can easily be taken apart again if required. The sides and top and bottom may either be grooved for the cross and upright pieces, or can be simply nailed to the latter. Fig. 3 shows the complete outside.

Deal tables are used in the photographer's work-room very frequently for a variety of purposes. Their usefulness is greatly enhanced by fitting a shelf under the table

per, midway between it and the floor. If the table is placed against a wall a piece of wood should be nailed to the back edge of top so as to form a fence, to prevent small articles from getting between table and wall. The fence is made about ten inches high, and a shelf, six or more inches wide is fastened on top of that supported by brackets at ends, no space is occupied, the table proper can often be kept much freer for work. It will frequently be found, however, that a fixed shelf can advantageously replace a table.

In the dark-room, shelves for the various bottles are, of course, imperative. The hypo dishes should be arranged over the sink. A hypo tank takes up less room than one, and will hold twelve plates. We have fixed on to

the outside of our sink at one end a square box of such a size that the tank just fits into it. All drippings drain off into the sink instead of running on to the floor, as when plates are removed from developer to the dishes.

It will be found, when one is fixing shelves into a small room, that high shelves seem to cut off space in a disagreeable fashion. If, however, the lower shelves only come three feet above the floor, and are continued again if necessary six feet above it, there seems practically no restriction of space. Of course, each will discover for himself the waste room that might make useful shelf-room, or the space occupied to poor effect that can be economised; but we hope these generalities will be sufficient to remind one of a matter that is too often "shelved."

## THE MODERN NOTE IN THE DESIGN AND FITTING OF PHOTOGRAPHIC PREMISES.

### II.

As to the matter of the nice appearance of the photographer's premises is an important one should be self-evident. When we consider that, by reason of the stress of modern competition, it becomes more necessary every day for the photographer, as well as for all others who cater for the public's wants, to make a living, to "put his best foot forward," and to give the best possible show of the wares he has to offer to the public who are constantly becoming better educated, better able to appreciate all that is pleasing and artistic, and without, none

possessed of more artistic knowledge) lag behind, with their ill-arranged windows and show-cases, often overcrowded with incongruous and ill-assorted specimens; and with their dusty and untidy reception-rooms and studios, often much too "photographic" in all senses of that much-abused word? That there are many exceptions to this state of things I am, of course, only too pleased to admit, but even among these exceptions one often sees little faults and shortcomings which might be easily remedied; and the places upon the design and arrangement of which

Fig. 5

Fig. 6

less keen in demanding value for their money. That such a display will be more readily attracted to an establishment which shows artistic taste in its surroundings and ensemble, as well as the work produced, than to one that in its designing and arrangement shows less of that quality than the confectioner's next door or the butcher's over the way, is surely the fact; while it should also be remembered that the work itself will look very much better if seen in an appropriate and artistic setting. Most photographers having come to this conclusion, why should photographers (who certainly should be, but often, I fear, are not,

little or no trouble has been spent by their proprietors are still far more common than they should be, either for the credit of their owners, or as a means of filling their pockets.

In this latter connection I am very emphatically of the opinion that it pays the photographer to have an artistically arranged and up-to-date place of business, and that the expenditure of some amount of thought and a little money on the matter is, in all cases, a good investment for him. Of course, only the minority can afford to employ eminent architects and first-class decorators, but all may study the rules of art and of good taste,

and each apply them according to the circumstances of his own case and position. It is by no means necessary that large sums of money should be spent to produce an artistic effect, and in many cases it is surprising what a little modification of existing conditions will often suffice to make an enormous amount of improvement in the appearance of a previously commonplace and even apparently unsuitable place. Paint, paper, canvas, draperies, and light woodwork are all very cheap, and with a little judicious employment of such things great transformations may often be very easily brought about. The main point is for the would-be improver to grasp clearly the principles which underlie the matter, and how best to apply them to the particular case with which he has to deal, and to afford some hints on these is the purpose of this and the following papers.

One of the first things to remember with regard to all decorative work is that you should ornament construction, and not construct ornament. To make sure of obeying this principle, the use and purpose of the thing under construction must first receive careful attention, it being an undoubted fact that anything which is absolutely and exactly fitted for its purpose will nearly always possess some element of beauty as well. This

Fig. 7.

"beauty of fitness" is, for instance, wonderfully illustrated in the honeycomb, in which you have the necessary cells constructed so as to give the maximum of holding capacity and strength with the minimum of material, and at the same time presenting on the surface a pleasing pattern of adjacent hexagons that has been used by artists and decorators of all ages and countries.

The principle of ornamenting construction and not constructing ornament, above referred to, being the basis of all good architectural and decorative effect, it must be especially kept in mind while we consider the problems with which we are here dealing, namely, how to make suitable and artistic the surroundings of an ordinary photographic business. The first point with regard to the latter is, naturally, how the work of the photographer may be set off to the best advantage. In an ordinary business this work may be considered to be generally of a monochromatic character, and to be, to a large extent, composed of portraiture. It will, however, vary considerably in tint, and also in size, so that these latter points must also be considered while means for its display are being arranged.

#### The Photographer's Shop Window.

The photographer's first and most important means of introducing his work to the notice of new clients is, of course, his shop window or show-case, and we will, therefore, proceed first to consider the design of such things. With regard to the first-mentioned of them, it may be at once said that a very large amount of space is by no means necessary,

or even desirable, for not only is a large sheet of plate-glass an unpleasing, ugly, and costly thing, but it is also usually very destructive of anything like good architectural effect in a building in which it occurs. It is also very difficult to fill a very large window satisfactorily with photographic work. If the window is tall and high, anything placed in the upper part of it is not only thrown out of perspective, but is also out of the range of vision of the passer-by, unless by unpleasant straining of the eyes and neck; so that in case such a window exists and cannot be altered, it is generally better to partially drape it and use the upper portion for the admission of light to the shop beyond than to place any specimens in such a bad position.

#### A Small Window is Better than a Large One.

A very large window also demands an undue number of specimens to fill it, which makes it a special disadvantage to photographers in the smaller provincial towns, where not only are sitters fewer, but where also a constant change of window dressing is more desirable than in the larger centres of population. Among a large quantity of work there must also, of necessity, be a greater chance of things which do not harmonise coming together, to the destruction of artistic unity of effect; to say nothing of inferior work having to be sometimes used to make out, which will, of course, lower the average of the whole. A large collection of portraits is also apt to be a weariness to the casual spectator, who would give a much more appreciative attention to a smaller collection of the photographer's best work. In a small window, too, the much more artistic system of only showing work in one process at a time may be adhered to, which not only is each display more harmonious in itself, but each can also have its proper and most suitable background and setting in the way of draperies, etc., and thus more striking and attention-arresting changes be constantly made, and a small quantity of the artist's best work thus effectively and tastefully arranged do him and his business a great deal more good than a large amount of inferior stuff going badly together, and some portion of it at least out of harmony with its surroundings.

#### Draperies for the Shop Window.

For these one-process displays, the window might be filled one week, for instance, with sepia carbon, another with blue platinotype, and another with matt silver prints, and so on, and for use with each might be made a set of window draperies harmonising in tint with the work to which they are to form a background. This idea is often carried out by such firms as Fullers, the well-known confectioners, and others, and, although the photographer should not use the brilliant colours which often suit their wares, he might well take hints from the softer and more delicate colourings used by Messrs. Waring, Liberty, etc., to show off their silver, pottery, and other artistic goods. I have said "should not" in the above sentence, because, as a matter of fact, I find that the photographer very often, when buying his window draperies and fabrics, forgets that they are not themselves the objects to be shown, but only the background and foil for his work, and so gets them much too strong and obtrusive in colour and effect, violating the principles of subordination and fitness with brilliant crimsons, electric blues, and even vivid greens which are totally out of harmony with every variety of his work. Instead of this, how much better delicate brown or creams to go with his carbons, ivory white or soft greys for his platinotypes, and whatever broken tints that may best harmonise with the colour to which he tones his silver prints. The variety of materials which may be used for the lining of showcases, or for window draperies, is very large, including holland, linens, canvases, plushes, velvets, and silks, and while the colour should harmonise with that of the work which they form a setting and background, it may be also laid down that the texture chosen should be proportionate, as it were, to the size of the pictures to be shown; a coarse canvas being, for instance, most suitable for going with large works, while smaller

re delicate pictures should be seen against finer and softer Enlargements generally look well against canvas, carbons and platinotypes against hollands and linens, prints against silks, and miniatures and coloured work plushes and velvets. It may also be added that the chosen should generally be without pattern, or at most a self-coloured one as may be found on some damasks and brocades, as any assertiveness or conspicuousness of design would detract from the restfulness which is necessary to backgrounds, and cause them to compete for the spectator's attention with the work that they should only unconsciously

general interior fittings, other than draperies, should be of wood, the restlessness and disturbing glitter of silk, mirrors, tiles and such-like things being scrupulously avoided. Palms, pot plants, and ferns are also undesirable to a photographer's window display, to say nothing of monstrosities as stuffed kittens and other *lusus nature*, I believe, are not unknown in such a position. The window enclosures must, of course, be in harmony with that of the shop front and that of the interior fittings. The shop itself as they are seen in conjunction with both, suggests us naturally to the next part of our subject, namely, the design of the exterior of shop-fronts and show-cases.

#### The Shop Window Exterior.

To illustrate these I have prepared sketches of one or two styles, four of which were given last week. The principles kept in mind in designing them are:—Simple, the avoidance of the glitter of metal or marble and over-elaboration of ornamental detail; and moderate size and cost. Where, as is most often the case, wood is the principal material, there is nothing better than good oak, left from the tool, and wax-polished, which will form a good and harmonious setting for most kinds of graphic work. For interior show-cases or fittings to hold prints, miniatures, or other small coloured work, darker such as rosewood, and a higher polish may often be used to advantage, but for exterior work I think that oak stands pre-eminent. A good example of it, both for interior and exterior, in connection with the display of photographic work, is seen in the alterations made to the Kodak Company's shop in Regent Street, from the designs of Mr. George Walton.

#### Some Designs of Shop Fronts.

The three designs, numbered Figs. 5, 6, and 7, are for show-cases, to be executed in wood. In order to save space, the two first have been drawn with the framework in larger proportion to the glass area than would be desirable in actual work, but as, in any case, they are only intended as suggestions, which might be modified to suit different spaces and conditions, this is not of importance. In all three cases they are fairly simple in construction, and could be made almost anywhere at moderate cost. The small amount of suggested ornamentation and lettering might be executed in paint, composition relief, or inlay, which represent, in the order given, differing degrees of increased expensiveness.

#### Styles in Painted Woodwork.

When painted woodwork is used, as will be very generally the case when existing premises have to be adapted, without much structural alteration, for photographic use, we are limited, by the necessity for harmony with the work to be displayed, to but a few tints, but still some very effective and artistic schemes may be worked out in ivory white, creamy white picked out with brown or Indian red, brown or dull black with warm white. Black, with a little gold, is also possible, but any brighter colours than those mentioned are usually to be avoided. Of course, such artistic abominations as any kind of graining or marbling will be eschewed by the modern man of any taste whatever. Any necessary metal work may be in wrought iron, finished either black or "armour bright," or of dull copper or bronze, but brilliantly polished copper or brass is generally out of place.

With regard to any lettering that may be required on any shop-front or show-case, the modern note of taste requires that it should be small in quantity, not too large in size, and of good artistic design in harmony with its surroundings, all of which qualities may be easily obtained without any sacrifice of due prominence or legibility.

With reference to the illustrations which accompany this article, it may be said that they have been prepared as suggestions only, but they make some attempt to show the various degrees of elaboration which may be considered appropriate to different situations and classes of business.

DRINKWATER BUTT, F.R.P.S.

(To be continued.)

## CONVERSATIONS ON COPYRIGHT.

### I.

RIGHT. The sole and exclusive right of copying, engraving, reproducing, and multiplying any photograph, and the sale thereof, by any means and of any size.—[Extract from Copyright (Works of Art) Act (1862).] This explicit definition of copyright from the Act, the present series of conversations will aim to convey by a series of examples and simple dialogue the way in which the law affects the photographer: I., as regards ownership of the right; II., as regards registration; III., as regards sale of the right; IV., as regards infringement of

copyright; and V., as regards copyright in foreign countries. We will ask the reader to assume that he is the querist (Q.) and that the answers (A.) are given to him (as they are) by one who has had cause to digest every sentence of the Copyright Act, and of the judgments in the courts, and has, moreover, for years past rarely passed a day without having some incident of a photographer's business in which copyright was concerned brought before him for his advice. In this first section of the subject, continued from last week, we deal with the ownership of copyright as it affects the photographer.

#### THE OWNERSHIP OF COPYRIGHT.

I should like to know how the photographer stands in relation to the copyright in photographs of babies or children who may die. To whom does the copyright belong?

It is not likely that persons of such extreme youth paid for photographs. Probably their parents did so, therefore the copyright remains in their possession.

Another case appears of importance. Suppose a photo-

grapher takes a sitter in several positions. To whom belongs the copyright in those which the sitter rejects?

A.: It was long ago held that such surplus negatives are exactly on all fours with those which the sitter chooses: the photographer must not use them or print from them without the sitter's permission. The reason for this is that in the taking of a photograph payment is for all attempts—for the

labour of the author, in short—and, therefore, the copyright is not vested in the photographer.

Q.: There is still another case. A person, A., brings a sitter, B., to the studio to be photographed, and orders some portraits. I suppose the copyright falls to A. in such a case?

A.: Certainly it does, if the photographs are taken to the order and at the expense of A.

Q.: Suppose the photographer takes one or two positions for himself?

A.: It has been held, that unless there is an agreement to the contrary, all the portraits taken at a sitting arranged in this way are the property of the person who orders the sitting.

Q.: What about groups, such as those of football clubs? Can we assume that, as there are so many persons concerned, the copyright is not owned by any one of them?

A.: Certainly not. Some one person—e.g., the secretary or treasurer of the club—is responsible for payment, and in this and similar cases the copyright belongs to the person responsible for paying the photographer.

Q.: Am I to suppose from what we have said that any payment of money to a portrait photographer by a sitter means that the copyright is therefore vested in the sitter?

A.: Not at all. If the photographer receives no payment for the sitting, the copyright falls into his possession. As it is his, he is therefore at liberty to sell prints to the sitter or to anybody else.

Q.: The "free sitting," in fact?

A.: Exactly.

Q.: Could it not be argued that the subsequent sale of prints constitutes a "valuable consideration"?

A.: It has been so argued, but the courts have decided otherwise; the Act expressly states that the *negative* shall be made or executed; in other words, the sitting given for a good and valuable consideration—i.e., if the copyright is to be the sitter's.

Q.: In thus acquiring the copyright, is the photographer precluded from receiving any money at all for the sitting?

A.: He may accept a reduced price; but in that, and indeed in any case where it is possible to assume he has been fully paid, he must get the sitter to transfer the copyright to him.

Q.: I should like to know how such an assignment should be worded.

A.: The following form shows the kind of agreement suitable for the purpose:—

To Mr. ....

In consideration of your allowing me a reduction from your usual terms for taking photographs of me or on my behalf this day, I hereby agree that the copyright in such photographs shall be reserved to you, and that I will not deal in any way with the photographs to prejudice your interest in the copyright.

Dated the.....day of....., 190.....

Signed.....

Witness.....

Q.: I take it that transference of the copyright in this way to the photographer deprives even the sitter of the right to allow the photograph to be reproduced.

A.: That is so; but photographers who work largely on the "free sitting" principle usually do not overstep the mark in exacting a fee for reproduction. It is usual, for example, to allow an actress to employ the photographer on her professional card, or in other circumstances in which, otherwise, she would have to pay for the reproduction.

Q.: Under the usual conditions of payment for the photographs, I understand that the copyright belongs to the sitter.

This means, I suppose, that if the sitter takes a print of a making to another photographer, he can have copies made, and I cannot prevent it.

A.: Of course you cannot. Your sitter has a perfect right to do what he likes with his own.

Q.: In the event of these (inferior) copies being placed, have known it done—in mounts bearing my name, have I a remedy for the damage to my reputation?

A.: Possibly you have, under plea of false trade description but the Copyright Act cannot help you.

Q.: If a sitter, as sometimes happens, is asked for a photograph of himself for reproduction, and if he places one by for which he has paid in the usual course, should he not state that my name as photographer is acknowledged in the matter?

A.: There is nothing in the Copyright Act to compel him to do so, nor is there any custom of the trade to suggest that he should do so. He is simply using what he has paid for, and if he does more, it is out of consideration for the photographer.
